Abstract

Sixty one core samples from three shallow core holes (Qusaiba-1, Baq'a-3 and Baq'a-4) penetrating the Qalibah Formation (Qusaiba Member) in North Central Saudi Arabia were investigated. These core slabs corresponding to grey-greenish hemipelagic shale or silty-shale yield well-preserved and very abundant early Silurian chitinozoans. Most of the recorded chitinozoan assemblages are diverse and include several new species occurring with well-known species. An informal early Rhuddanian chitinozoan assemblage dominated by *Cyathochitina caputoi* is documented in the lowermost part of the Qusaiba Member. The six chitinozoan biozones defined above this basal assemblage range from Aeronian to Telychian. They are considered of regional value for northern Gondwana. From the lowest to the highest they are the *Angochitina qusaibaensis* (*pro parte*), *Conochitina alargada*, *Angochitina*

hemeri, *Angochitina macclurei*, *Tanuchitina obtusa* and *Euconochitina silurica* biozones. The older regional biozones have been previously documented in Saudi Arabia whereas the two youngest ones, the eponymous index species of which were described from the subsurface of the Algerian Sahara, are documented for the first time in the Arabian Peninsula. Four subbiozones, of at least of regional application, are also defined in order to improve the precision of biostratigraphic correlation between Silurian lithostratigraphic units cropping out along the Arabian Shield and their counterparts in the subsurface of Central Saudi Arabia. Thanks to closely spaced and to regular sampling, the total range of several highly diagnostic forms as well as the interval of uncertainty between the successive chitinozoan biozones are better constrained. A hiatus with a duration of late Rhuddanian to early Aeronian separates the lowest informal chitinozoan assemblage from the *qusaibaensis* Biozone. A recent detailed study of the graptolites in the three cored holes provides independent chronostratigraphical control calibrating the previous chitinozoan-based age assignments. The *qusaibaensis* (pro parte), the *alargada*, and the *hemeri* chitinozoan biozones occur with the mid Aeronian *convolutus* graptolite Biozone whereas the *macclurei* chitinozoan Biozone extends through the early Telychian *guerichi* and *turriculatus* graptolite biozones. The *obtusa* and the *silurica* chitinozoan biozones occur in an interval devoid of usable graptolites. They are referred to the mid-late Telychian as they do not contain typical Sheinwoodian species.

Beside abundant chitinozoans and acritarchs, sporadic occurrences of scolecodonts and of eurypterid cuticle fragments are also noted in the organic residues. The presence of eurypterids reflects a shallowing trend in the sedimentary record, which is consistent with the distribution of the graptolites remains (sicalae and/or rhabdosomes). Indeed, graptolites are common throughout the Qusaiba Member, except in the youngest processed samples presaging the shallower environments prevalent in the Sharawra Member. The taphonomy of

the chitinozoans (isolated vesicles, chain-like structures, clusters, coprolites) and their environmental context are briefly discussed.

Fifteen new species are described and illustrated: *Ancyrochitina alhajrii* sp. nov., *Ancyrochitina camilleae* sp. nov., *Armoricochitina crassicarinata* sp. nov., *Armoricochitina gengi* sp. nov., *Bursachitina baqaensis* sp. nov., *Conochitina viiuae* sp. nov., *Cutichitina minivelata* sp. nov., *Cyathochitina neolatipatagium* sp. nov., *Fungochitina merrelli* sp. nov., *Muscochitina olivieri* sp. nov., *Plectochitina alisawyahensis* sp. nov., *Plectochitina alnaimi* sp. nov., *Plectochitina jaquelineae* sp. nov., *Plectochitina lucasi* sp. nov., and *Spinachitina geerti* sp. nov.

Key words: Chitinozoans, Biostratigraphy, Systematics, Palaeoenvironments, early Silurian, Saudi Arabia, Northern Gondwana

1. Introduction

Under the auspices of the Commission Internationale pour l'étude de la Microflore du Paléozoïque (CIMP) a multi-disciplinary project with Saudi Aramco was initiated in the early 1990s for documenting organic-walled microfossils and biostratigraphy from the Ordovician and Silurian formations from Saudi Arabia. One of the goals was to develop a robust regional chitinozoan biozonation allowing correlation between the strata exposed along the margin of the Arabian Shield and the Early Palaeozoic units including source rocks and reservoirs buried beneath a Mesozoic and Cenozoic cover in central and southern Saudi Arabia (Fig. 1a). The first step is to establish and calibrate the chitinozoan biozones from the type areas of the

Ordovician and Silurian formations and members exposed in the north-western part of Central Saudi Arabia. In Saudi Arabia, as in most of the tropical and sub-tropical desert regions, deep surficial weathering affects much of the exposed sedimentary rocks. This weathering proved to be responsible for the partial to total destruction of organic-walled microfossils and of the amorphous organic matter. In order to overcome this weathering phenomenon, shallow cores were drilled in the type area of the Qusaiba Member of the Qalibah Formation. They have been sampled and studied for the chitinozoans and other organic-walled microfossils (see this volume).

As far as chitinozoans are concerned, the Qalibah Formation is the most extensively investigated among the Saudi Arabian Early Palaeozoic lithostratigraphic units. The data are available in the following papers (McClure, 1988; Aoudeh and Al-Hajri, 1995; Paris et al., 1995; Paris and Al-Hajri, 1995; Al-Hajri and Paris, 1988; Paris et al., 2008) as well as an unpublished thesis (Al-Hajri, 1991) and numerous Saudi Aramco internal reports (more than 300 internal reports). The goal of the present study is to refine the northern Gondwana chitinozoan biozonation based on the Saudi Arabian collections with the introduction of new biozones and subbiozones applicable to the Arabian palaeoplate. Graptolites present in part of the section investigated (Zalasiewicz et al., 2007) give precise ties with the standard graptolite biozones) and consequently with the series and stages of the standard Silurian chronostratigraphy (Zalasiewicz et al., 2007, 2009). In addition, because the recorded material is abundant and very well-preserved, the present investigations provide helpful information about intraspecific morphologic variations of several critical species, especially for the index species of previously and newly identified biozones and subbiozones. The generally close sampling and the partial overlap of the three selected boreholes help refining of the ranges of the most significant index species.

A more precise correlation with some incompletely understood chitinozoan assemblages is proposed (e.g. from the ISWH EW-9 well; see Paris, 1993) in terms of the early Silurian regional chitinozoan biostratigraphy of Saudi Arabia.

2. Material and technical procedures

2.1. Samples

Sixty one core samples were collected from the Qusaiba-1, Baq'a-3 and Baq'a-4 shallow core holes that penetrated the Qusaiba Member of the Qalibah Formation (Figs. 1a, 2). The Qusaiba-1 well was drilled in the Qusaiba type area, in north-western Central Saudi Arabia (Figs. 1a–b). The Baq'a-3 and Baq'a-4 shallow core holes are located to the north (Figs. 1a, c), in the type area of the latest Ordovician Baq'a Member of the Sarah Formation. In each borehole the sampling was regularly distributed and quite closely spaced in order to reduce the intervals of uncertainty between successive chitinozoan assemblages. The 28 samples from the Qusaiba-1 core hole are distributed (mean interval of 5 ft, ca. 1.5 m) through a 124.35 ft thick sequence extending from 132.05 ft to 256.40 ft (Figs. 3, 9). The three oldest samples (core 27 at 256.4 ft, 255.15 ft and 254.8 ft) are documented and used for defining the Ordovician-Silurian boundary (see Paris et al. this volume). The 13 samples from the Baq'a-4 well (Figs. 4, 9) range through a 228.9 ft thick sequence from core 7 (40.1 ft) to core 31 (269 ft). In the Baq'a-3 well (Figs. 5, 9) the 20 collected samples are less densely distributed (interval close to 20 ft, ca. 6 m) along a 388.3 ft thick sequence from core 14 (130 ft) to core 56 (518.3 ft). The lithology of the core slabs is rather homogenous, especially in the lower part of the three boreholes (Tables

1–3). In general samples are grey to greenish or grey-greenish shale. Slight lithological variations are recognized for example in the lowermost part of the Qusaiba-1 (carbonaceous shale from 256.4 ft to 254.8 ft) and silty shale intervals in the upper part of the Qusaiba-1 (136.5 ft to 132.05 ft) and in the Baq'a-3 core holes (cores 25 and 27). These lithological variations indicate shallowing of the palaeoenvironments. In the upper sample (core 14) from the Baq'a-3 well this shallowing trend is more conspicuous and announces the boundary between the Qusaiba and the Sharawra members. A significant increase of eurypterid cuticle fragments, and possibly of plant remains, confirms this shallowing trend in the upper part of the Baq'a-3 core hole (cores 14 to 21; Table 2). A concomitant disappearance of the graptolites is noted in these more shallow environmental settings (Tables 1 and 3). It is noteworthy that graptolites are not documented from the Sharawra Member (Al-Hajri and Paris, 1998, and unpublished data).

The absence of well-developed early Silurian black shale facies in the investigated cores is stressed. The only significant gamma ray peak is located at the carbonaceous shaly level at 254.8 ft in the Qusaiba-1 core hole. This thin interval (possibly condensed) in the lowermost part of the Qusaiba Member (see Melvin, this volume) yields lowermost Rhuddanian chitinozoans in great abundance (Fig. 6; Table 19). This chitinozoan assemblage, discussed in detail in Paris et al. (this volume), occurs below a hiatus (gap) that separates these Rhuddanian deposits from the mid-Aeronian graptolitic shale.

2.2. Technical procedure

2.2.1. Bedding plane observations

All of the samples were examined using a binocular microscope at low to medium magnification (16 x or 40 x) prior to the crushing of the rock sample. The bedding plane surfaces of the core slab were wetted with alcohol in order to increase the contrast and to more easily recognize macrofossils and small organic remains. These observations revealed the occurrences of inarticulate brachiopods, ostracods and graptolites (sicalae and rhabdosomes). Microfossils and larger organic-walled fossils, i.e. scolecodonts, plant, fragments, eurypterid cuticles and chitinozoans (as isolated vesicles, catenary structures, clusters and even coprolites comprised of crushed chitinozoans) were present with minerals (e.g., pyrite, heavy minerals, graphite) (Tables 1–3). The observation of the rock samples revealed that organic-walled microfossils are frequently concentrated on very thin darker bedding plane surfaces.

2.2.2. *Acid treatment and microfossil sorting*

The procedure described by Paris (1981, 2006) for the isolation and preparation of chitinozoans was used. The technique is based on handpicking of all, or more frequently of a measured percentage of the specimens present in the palynological residue. The picking under a stereoscopic binocular microscope is accomplished using a finely drawn glass micropipette. After sorting a quantified fraction (depending on the abundance of the recovered chitinozoans) or the entire chitinozoan population from the residue of a sample, the picked vesicles are mounted as permanent palynological slides in Canada balsam. The identification of the species and counting of the specimens is made using these slides, whereas the best-preserved or the most significant individuals are separately prepared for SEM examination. After SEM observations and photomicrography, these individuals are also mounted as permanent palynological slides in Canada balsam according to the technique described in Paris (1978). This allows a secure preservation of the type material and

illustrated individuals. Moreover it is possible to precisely relocate these specimens in the palynological slides with England Finder coordinates (see captions of Plates 1-18). In some cases (e.g., very abundant chitinozoans; new species) additional slides of selected specimens are prepared also.

2.2.3. Specimen counting and repository

Chitinozoans were too numerous in some samples for a complete inventory of all specimens (e.g. more than one thousand specimens per gram of rock in samples from 254.80 ft and 140.10 ft in Qusaiba-1, 289.1ft in Baq'a-3, and 261.2 ft in Baq'a-4). In such very rich residues, the picking and the counting were made from 20%, 10% or even 2 % of the residue (Tables 1–3). The chitinozoan abundance is expressed as number of specimens per gram of rock (Figs. 6–8). The relative frequency (as a percentage) was calculated for each identified chitinozoan taxon and for undetermined specimens. The relative abundances and the stratigraphic ranges for each species recorded for the three investigated wells are given on these range diagrams. All of the palynological preparations, including those with the illustrated material, are stored in the collections of Geosciences/OSUR (CNRS, Observatoire des Sciences de l'Univers de Rennes) at the University of Rennes (France) under the repository numbers IGR 72201 to 72300 for the Qusaiba-1 core hole, IGR 72301 to 72346 for the Baq'a-3 core hole and 72351 to 72376 for the Baq'a-4 core hole. These palynological slides and the corresponding SEM photos are registered in the “CHITINO_IGR” and in the “PHOTOCHITINO” databases of F. Paris.

3. Chitinozoan biostratigraphy

The proposed biozones and subbiozones are based on the First Appearance Datum (FAD) of selected index taxa or on the total range of the index species. This local biozonation is correlated with the regional Silurian chitinozoan zonation published by Paris et al. (1995) for Saudi Arabia. The chronostratigraphical age assignment is based on the graptolite zonation provided by the well-preserved, numerous, but often low diversity graptolite assemblages (Zalasiewicz et al., 2007) present with the chitinozoans in many samples from the Qusaiba-1, Baq'a-3 and Baq'a-4 cores. Calibration of the Saudi Arabian regional chitinozoan biozonation of Paris et al. (1995) and correlation with the global Silurian chitinozoan zonation of Verniers et al. (1995) are significantly improved in terms of standard graptolite zones. The precision of these graptolite/chitinozoan biozones ties is comparable to that published by Loydell et al. (1998, 2003, 2010) for the Silurian of the Baltic area.

The average sampling interval is less than 6 ft in the Qusaiba-1 well (Table 1; Fig. 3). In the two Baq'a core holes it is approximately 20 feet (Tables 2–3; Figs. 4–5) and is too large for an exact location of the FADs and LADs of the selected index species. This introduces intervals of uncertainty of a few meters thickness. Additional regional control on the respective range of the species is possible because the stratigraphic intervals investigated in the three shallow cores partly overlap those studied previously in the deep boreholes of Central Saudi Arabia e.g., UDYN-1, TINT-2, NYYM-2 (Paris, 1991, 1992; Paris et al., 1995) and ISWH EW-9 (Paris, 1993) (see Fig. 1a). Some of the taxa reported in open nomenclature or as *nomina nuda* in previous internal reports for Aramco (Paris, 1991, 1992, 1993, 2003, 2005) are formally described and biostratigraphically constrained here. McClure (1988) and Al Hajri (1991) have already illustrated several of these new species. The abundant populations recovered allowed a biometric evaluation of vesicle dimensions (Tables 4–18,

Figs. 10–24).

The regional biozones and their subbiozones are defined and discussed in ascending stratigraphic order. Previously used chitinozoan biozone names are favoured. They are documented from diverse and abundant chitinozoan populations (usually more than 100 chitinozoans per gram of rock, and in a few cases more than 1000 individuals per gram of rock). The percentage of the indeterminate specimens is fairly low (usually less than 20% of the populations).

3.1. “Assemblage 1”

This chitinozoan assemblage is restricted to the lowermost part of the Qusaiba-1 core hole (core 27 at 256.4 ft, 255.15 ft and 254.8 ft; see Figs. 3 and 6) of the Qusaiba Member of the Qalibah Formation. It is only briefly mentioned here because it is defined elsewhere in this volume when documenting the boundary between the Sarah and the Qalibah formations in the Qusaiba-1 core hole (Paris et al., this volume). *Cyathochitina caputoi* (see Paris et al., this volume; pl. VI, figs. 1–3, 5) dominates this low diversity assemblage but with extremely high chitinozoan abundance in the dark carbonaceous shale at 254.8 ft (more than 9000 chitinozoans per gram of rock). *Belonechitina pseudarabiensis* (see Paris et al. this volume; pl. VI, figs. 6, 9–10) is another important species of this “assemblage 1” (sensu Paris et al., this volume) as it occurs in the lower Rhuddanian of Jordan (Butcher, 2009), and is associated with very abundant *Cyathochitina caputoi* in the Nseirat section in Mauritania (Paris et al., 1998). In both localities it is associated with graptolites of the *ascensus* and/or *acuminatus* zones (see discussion in Paris et al., this volume). The 3.5 ft thick highly bioturbated and condensed horizon yielding this assemblage is bracketed between the top of the Baq’a Sand

Member of the Sarah Formation and a one foot thick bioturbated sandy bed at 253.5 ft corresponding to the first Aeronian deposits (see discussion in Melvin, this volume). A hiatus is interpreted to be present within the lowermost part of the Qusaiba Member at ca. 253.5 ft.

3.2. *The Angochitina qusaibaensis interval-range Biozone*

Definition. The definition of the *qusaibaensis* Biozone is slightly emended here. Originally, as defined by Paris et al. (1995), it corresponded to the interval-range biozone between the last occurrence (LAD) of *Lagenochitina nuayyimensis* Paris and Al-Hajri, 1995 and the first appearance (FAD) of *Conochitina alargada* Cramer, 1967. Because of the spacing of the samples available in the type locality (well NYYM-2), an interval of uncertainty existed at the base and at the top of this *qusaibaensis* Biozone. Consequently, based on recent data, the *qusaibaensis* Biozone is redefined here as the interval-range biozone between the FAD of *A. qusaibaensis* and the FAD of *C. alargada*, which is the index species of the overlying biozone. In the Qusaiba-1 core hole much of the lower part of the *qusaibaensis* Biozone is missing (see above) and only its uppermost part is represented from 251.10 ft to 245.8 ft (Figs. 6 and 9).

Main components. In the Qusaiba-1 well, the base of the Qusaiba Member is located in core 27 at 257.0 ft (see discussion in Melvin, this volume). In the same core, at 256.4 ft, 255.15 ft and 254.8 ft, a distinctive chitinozoan assemblage from the basal beds of the Qusaiba Member dominated by *C. caputoi* is referred to the earliest Rhuddanian (see above, and Paris et al., this volume). Sedimentologic and ichnologic evidence indicates a hiatus at 254.5 ft (Melvin, this volume). Immediately above this hiatus is a highly bioturbated sandy bed (ca. 1 ft thick) directly overlain by typical Qusaiba shaly lithofacies (Fig. 3). The first sample available from

these shales is 3.4 ft above the hiatus and yields an abundant and diverse chitinozoan assemblage typical of the *qusaibaensis* Biozone (Fig. 6). Most of the specimens of *A. qusaibaensis* (25% to 36%) recorded in the lower part of the Qusaiba Member show a rather long neck (Plate I, 5; Plate II, 6–9) recalling those of *A. hemeri*. The chamber of *A. qusaibaensis* has no true spines but the distinction between the two species may be difficult when the ornamentation is partly eroded. A peculiar structure, never previously reported, is visible on many specimens of *A. qusaibaensis* from the lower samples in the Qusaiba-1 well. This unnamed structure consists of a very long membranous tubular sleeve (as long as the vesicle) extending from the prosome through the aperture (Plate II, 6a–b, 9). It is not known if this structure has a taxonomic significance (e.g., only present in a transitional form between *A. qusaibaensis* and *A. hemeri*) or if it is the result of excellent preservation related to very quiet depositional environments. Occurring with the dominant *A. qusaibaensis*, classical Aeronian components occur such as *C. edjelensis* (17%; Plate I, 8), *P. pseudoagglutinans* (Plate I, 7), *Belonechitina arabiensis* (11% at 248.3 ft) and *C. caputoi* Da Costa, 1971 (13% at 245.8 ft; Plate II, 1-2). Among the subordinate species present are fairly rare but usually long ranging taxa occur (Fig. 6; Table 19), e.g. *Pterochitina deichaii* Taugourdeau, 1963 (Plate II, 3), *Cutichitina minivelata* sp. nov., *Calpichitina* sp. aff. *C. densa* (Eisenack, 1962), *Conochitina vitrea* Taugourdeau, 1962 and *C. elongata* (Plate I, 3–9). Stratigraphically of greater interest is *Muscochitina olivieri* sp. nov. (20% at 251.1 ft; Plate I, 1, 4), as this new species seems restricted to the upper part of the *qusaibaensis* Biozone. It was recorded but not illustrated (“*Sphaerochitina* sp. 2” among the reported *Sphaerochitina* sp. indet., see synonymy list and discussion below in the Systematic section) in the subsurface of Central Saudi Arabia (UDYN-1, core 17 at 16.635.7 ft, and TINT-2, core 20, at 16.872 ft) (Paris, 1991, 1992). A last species is *Conochitina viiuae* sp. nov. a long slender species (Plate I, 2; Plate II, 4-5), abundant at 245.8 ft (15%; see Fig. 6).

Range. In the Qusaiba-1 well, the *qusaibaensis* interval-biozone extends from 251.1 ft to 238.2/6 ft where the lowest occurring *C. alargada* are recorded (Fig. 6; Table 19). The base of the biozone is poorly defined in the NYYM-2 well (Paris et al., 1995, p. 81). Recent investigations on the chitinozoans of the Murzuk Basin, SW Libya (Paris et al., 2012) have shown that *A. qusaibaensis* is not associated with *L. nuayyimensis* at least in the main range part of the latter species. This is consistent with the range of *A. qusaibaensis* in UDYN-1, where no specimens of *L. nuayyimensis* have been recorded (Paris et al., 1995). Because of the restricted range of *M. olivieri* sp. nov., identified as “*Sphaerochitina* sp. indet.” in the upper investigated cores of wells TINT-2 (core 20, at 16.872 ft; Paris, 1992) and UDYM-1 (core 17 at 16.635.7 ft; Paris, 1991), it is considered that only the upper part of the *qusaibaensis* Biozone is represented in the Qusaiba-1 core hole.

Age assignment. In a previous paper, the base of the *qusaibaensis* Biozone was referred to the upper Rhuddanian, based on the occurrence of graptolites of the *cyphus* Biozone in its lowermost part in the TAYMA-1 well (see Paris et al., 1995, p. 81). The age of the upper part of the *qusaibaensis* Biozone, however, was not firmly constrained due to a sample gap at its highest occurrence in the NYYM-2 well, and to the absence of direct ties with graptolites or other fossils of stratigraphic value. The whole biozone was therefore tentatively referred to the upper Rhuddanian-lower Aeronian (Paris et al., 1995, fig. 4). The present material provides a much more precise calibration of the upper part of the *qusaibaensis* Biozone based on the graptolites of the *convolutus* Biozone recorded by Zalasiewicz et al. (2007) in the Qusaiba-1 core hole (Fig. 9). The interval attributed to the upper part of the *qusaibaensis* interval-biozone (251.10 ft to 254.6 ft) yields graptolites of the *convolutus* Biozone, hence we can conclude that the *qusaibaensis* interval-biozone ranges from the upper Rhuddanian (upper part

of the *cyphus* Biozone) to the mid-Aeronian (lower part of the *convolutus* Biozone). *M. olivieri* sp. nov. with a range apparently restricted to the upper part of the *qusaibaensis* Biozone, could represent a key chitinozoan species to indicate the early mid-Aeronian (i.e., lower part of the *convolutus* Biozone). It allows for instance to assign an early mid-Aeronian age for core 17 from the UDYN-1 well, and also for core 20 from the TINT-2 well. Nevertheless, an *olivieri* subbiozone is not yet proposed as the FAD of *M. olivieri* sp. nov. is not completely documented (hiatus in the Qusaiba-1 core hole; see above).

3.3. The *Conochitina alargada* total-range Biozone

Definition. This biozone is a close equivalent to the “*Conochitina alargada* - *Plectochitina paraguayensis* concurrent-range biozone” of Paris et al. (1995). The closely spaced samples and the good graptolite control available in the Qusaiba-1 core hole, lead to a minor emendation of the original definition. The *alargada* Biozone is defined here as the total-range biozone of *C. alargada* Cramer, 1967. In the Qusaiba-1 core hole, the base of this chitinozoan biozone is located 15.3 ft (ca. 4.6 m) above the base of the Qusaiba Member at 238.2/6 ft. The index species is moderately abundant in this sample (15% of the assemblage) but dominates the chitinozoan assemblage recorded at 235.4 ft (37%). *C. alargada* has its LAD at 210.9 ft with moderate to low abundances (Fig. 6). The top of the biozone is fixed at 210.9 ft in spite of the presence in this sample of very rare *A. hemeri*, the index species of the succeeding biozone (Figs. 6 and 9). The *alargada* Biozone as defined here corresponds to “Assemblage 2” (=“*alargada-paraguayensis* interval-range biozone”) of Paris (2003).

Main components. The chitinozoan assemblages recorded in the *alargada* Biozone are diverse with up to 12 species (Fig. 6; Table 19). *Angochitina qusaibaensis* is the dominant

species as it is the case in the underlying biozone (50% of the chitinozoans at 228.8 ft and 44% at 225.5 ft) (Fig. 6). *Conochitina alargada* is moderately abundant (1% to 15%), except at 235.4 ft (35%) and in the upper part of the biozone where *C. alargada* represents less than 5% of the recorded species. *C. edjelensis* (14% at 231.4 ft), and *Plectochitina pseudoagglutinans* (Plate III, 7-8; 39% at 238.2/6 ft and 38% at 217.2 ft) are the other most common components (Fig. 6; Table 19). Subordinate species are fairly rare (usually less than 3%) and long ranging taxa (Fig. 6; Table 19), as e.g. *B. arabiensis*, *P. deichaii* (Plate III, 11), *Cutichitina minivelata* sp. nov., *Belonechitina paravitrea* Paris and Al-Hajri, 1995 (Plate III, 3) and *C. sp. aff. C. densa* (Plate III, 5). Another species, *Cutichitina minivelata* sp. nov. (Plate III, 9), shows a fluctuating abundance, ranging from none at 238.2/6 ft to 12% at 225.5 ft. At the top of the biozone, at 210.9 ft, *Plectochitina alnaimi* sp. nov., a small form with bi-rooted processes and blunt cones or granules on the chamber (Plate III, 6), is abundant (23% at 210.9 ft) (Fig. 6; Table 19). This new species should be a useful guide for locating the top of the *alargada* Biozone.

Range. In the Qusaiba-1 core hole, the *alargada* interval-range biozone extends from 238.2/6 ft to 210.9 ft. The boundary with the overlying *hemeri* Biozone is not “sharp” as the first undisputable specimens of *A. hemeri* are observed at 210.9 ft, i.e. together with the last recorded *C. alargada* (Fig. 6; Table 19). In this sample *A. hemeri* is extremely rare (ca. 0.2% of the recorded chitinozoans) where *A. qusaibaensis* still represents 9% of all the chitinozoans recorded in this sample (see Fig. 6).

Age assignment. The graptolites of the *convolutus* Biozone identified by Zalasiewicz et al. (2007) in the Qusaiba-1 core hole provide a robust age control for the *alargada* Biozone as presently defined. The whole Qusaiba succession yielding chitinozoans of the *alargada*

Biozone are unambiguously of mid-Aeronian age. This precise graptolite control also allows a mid Aeronian age to be assigned to some well-known, but previously poorly stratigraphically controlled species such as *C. edjelensis*, *C. elongata*, *C. vitrea*, *P. deichaii* and *P.*

pseudoagglutinans described by Taugourdeau (1962, 1963) in south-eastern Algerian Sahara, Edjelé area, well D1-101, samples at 2863 ft (871 m) and 2761 ft (840 m) depth. Similar assemblages occur also in Cyrenaica (eastern Libya) (Molyneux and Paris, 1985; Paris, 1988)

3.4. *The Angochitina hemeri Biozone*

Definition. This biozone is defined here as the interval-range biozone between the first significant (more than 3%) occurrence of *A. hemeri* and the FAD of *A. macclurei* Paris and Al-Hajri, 1995. It corresponds to the two former regional biozones defined by Paris et al. (1995) and respectively labelled “concurrent range biozone of *Sphaerochitina solitudina* and *Angochitina hemeri*” and “interval zone of *A. hemeri*”. These biostratigraphic subdivisions were defined from samples of cores 18 and 17 of the TINT-2 well, where an uncored interval of about 83 ft (25 m) separates the last occurrence of *A. hemeri* from the first occurrence of *A. macclurei*. The material recovered from the Qusaiba-1 and Baq’a-4 core holes provides the missing information about this critical sample gap in the TINT-2 well and permits a much more accurate control on the base and on the top of the *hemeri* Biozone.

Main components. In the Qusaiba-1 core hole, *Angochitina* species (Plate I, 5; Plate II, 6–8) with the general morphology of *A. hemeri* (i.e., ovoid chamber with a long and slender neck) but with blunt spines or tubercles recalling the ornamentation of *A. qusaibaensis* are already present in the lowermost part of the Qusaiba Member. These puzzling specimens make it difficult to locate precisely the FAD of *A. hemeri* in the Qusaiba-1 core hole, where very rare

(0.2%) specimens are recorded at 210.9 ft. Typical specimens of the index species from the sample at 176.05 ft are illustrated (Plate IV, 5–6; Plate V, 1). In the Baq'a-4 core hole A. *hemeri* may be abundant (39 % of the identified individuals at 140.6 ft; Fig. 7; Table 20) where it coexists with very rare *C. alargada* (Plate VIII, 4), *B. paravitrea* (Plate VIII, 5, 8), and *B. arabiensis* (1% of the recorded species). *Plectochitina alnaimi* sp. nov. (Plate IV, 9; Plate V, 2, 10), already present in the underlying biozone, is the most abundant species (from 17% at 167.7 ft to 70% at 140.1 ft) from the lower part of the *hemeri* Biozone in the Qusaiba-1 core hole (Fig. 6). It can be considered as an auxiliary species for identifying the lower part of the *hemeri* Biozone.

Other species are restricted to a single sample, where they can be abundant. *Linochitina?* sp. (Plate VI, 1–2) is reported only in core 14 at 132.05 ft (29% of the recorded chitinozoans; Fig. 6). This form is kept in open nomenclature because the copula normally present in *Linochitina* species has not been observed (it might alternatively be referred to as an *Euconochitina*). *Anthochitina primula* Nestor, 1994 is exclusively recorded at 145.9 ft in the Qusaiba core hole. This species with a distinctive serrate or denticulate carina (Plate V, 3, 11–12) represents 13% of the chitinozoans from this sample (Fig. 6). In the Baq'a-4 well, the most dominant species is *Ancyrochitina* gr. *aculeata* (up to 68% of the identified specimens). Other species may be sporadically abundant in this well, such as *C. caputoi* (48% at 269.0 ft in the deepest investigated sample), or *P. deichaii* (13% at 269.0 ft) but discontinuously represented stratigraphically higher (Fig. 7; Table 20). *Spinachitina geerti* sp. nov. (Plate VII, 1, 4–5, 7–8) is an interesting and fairly short ranging species, recorded only at 240.7 ft and 163.0 ft in Baq'a-4 (Fig. 7). *Plectochitina paraguayensis* Wood and Miller, 1991 (Plate IV, 7–8; Plate V, 5, 9) has its FAD at 240.35 ft (10%) in the Qusaiba-1 well and is moderately abundant (4 % to 18%) up to 145.9 ft. *Plectochitina* cf. *clathrospinosa* (Plate V, 6) has very rare (less the 1%) and sporadic occurrences in the youngest samples of this Qusaiba-1 well

(Fig. 6; Table 19). The isolated occurrence of very abundant *Cyathochitina* cf. *caputoi* (Plate IV, 1) at 167.7 ft is striking. This increase in abundance may be related to environmental changes more favourable for *Cyathochitina* species as e.g. *Cyathochitina neolatipatagium* sp. nov. (Plate VI, 7–8, 11) is also the dominant chitinozoan species (71% at 134.2 ft and 59% at 133.45 ft) in the upper part the Qusaiba-1 core hole (Fig. 6). Männil (1971) had already pointed out such abundant but sporadic occurrences of *Cyathochitina* species in Baltoscandia.

Range. The first undisputable *A. hemeri* specimens are identified at 210.9 ft. Because the index species is too rare in this sample (0.2% of the recorded chitinozoans), and for practical reasons of identification, the base of the biozone is fixed at 204.35 ft. The species is well-represented from 176.05 ft to 132.05 ft (highest processed sample) in the Qusaiba-1 core hole and is abundant from 269.0 ft to 140.6 ft in the Baq'a-4 well (Fig. 7; Table 20). It must be stressed that a few *A. macclurei* precursors (Plate VII, 3) occur in the upper part of the *hemeri* Biozone in Baq'a-4 (Fig. 7), whereas the base of the succeeding *macclurei* Biozone is located at 140.6 ft in the Baq'a-4 core hole. In this well, indisputable *A. macclurei* specimens are associated with abundant representatives of *A. hemeri* at 140.6 ft. Consequently, the total-range of these two biozonal index species overlaps slightly. In the Baq'a-4 well the *hemeri* Biozone extends in the Qusaiba Member, at least along a 106 ft (ca. 32 m) thick sequence from 269.0 ft to 163.0 ft, and possibly more, as there is an interval of 22.4 ft without available samples. The strata corresponding to the FAD of the index species were not penetrated in this well. In the TINT-2 well the biozone was documented in a 83 ft (25 m) thick interval. *A. hemeri* (see synonymy in Paris and Al-Hajri, 1995) was originally called “*Sphaerochitina longicollis* form B” in Paris (1992).

Age assignment. The *hemeri* Biozone was tentatively referred to the early Telychian by Paris

et al. (1995) based on the known range of accompanying chitinozoan species in Baltoscandia (Nestor, 1982, 1990, 1994), and recently calibrated by means of graptolites zones (Loydell et al., 1998, 2003, 2010). In the present study numerous graptolites of the *convolutus* Biozone identified by Zalasiewicz et al. (2007) in the Qusaiba-1 well, in core samples yielding chitinozoans of the *hemeri* Biozone, provide robust independent age control. Based on these graptolite data, the *hemeri* Biozone is at least partly of Aeronian age. The upper part of the *hemeri* Biozone is present in the Baq'a-4 core hole, but only the oldest investigated sample at 269.0 ft yields graptolites firmly assigned to the *convolutus* Biozone (Zalasiewicz et al., 2007, fig. 6). In this latter well, the graptolites accompanying the chitinozoans corresponding to the remaining upper part of the *hemeri* Biozone (up to 163.0 ft) are only tentatively referred to the *convolutus* Biozone. Therefore, it is not excluded that the *hemeri* Biozone may extend into the lower Telychian. The occurrence of *Spinachitina geerti* sp. nov. at 240.7 ft and 163.0 ft in the Baq'a-4 core hole is of interest as in Belgium, this new species originally identified as *S. spinosa nomen nudum* in Van Grootel (1990), extends into the *sedgwickii* graptolite Biozone and in part of the *crispus* graptolite Biozone. It is worth noting that *Anthochitina primula* (restricted occurrence at 145.9 ft in the Qusaiba-1 core hole) was described by Nestor (1994, pl. VIII, figs. 1-6) from the uppermost part of the Velise Formation (sample at 140.1 m) in the Viki core hole, in Estonia. This sample was assigned to the lower part of the Adavere Baltic stage correlated with the *turriculatus* graptolite Biozone (see Nestor, 1994, fig. 28). *A. primula* is likely present in Québec, in the Jupiter Formation of similar age (Achab, 1981).

3.5. *The Ancyrochitina camilleae subbiozone*

Definition. This local subbiozone corresponds to the total-range of *Ancyrochitina camilleae* sp. nov. (Plate VIII, 1, 6) documented in the Baq'a-4 core hole (Fig. 7; Table 20). It

characterizes the uppermost part of the *hemeri* Biozone and does not extend into the *macclurei* Biozone.

Main components. Most of the species recorded in the lower part of the *hemeri* Biozone, e.g. *A. hemeri*, *B. paravitrea*, *B. arabiensis*, *A. gr. aculeata*, extend into this subbiozone. In addition to *A. camilleae* sp. nov., another short ranging species, *Bursachitina baqaensis* sp. nov. (Plate VIII, 3) and an atypical specimen of *S. cf. geerti* sp. nov. (eroded spines?; Plate VIII, 2) are restricted to the subbiozone and therefore are representative of the uppermost part of the *hemeri* Biozone.

Range. The *camilleae* subbiozone ranges at least on 38.2 ft (i.e. 11.6 m) in the Baq'a-4 shallow core (from 201.2 ft to 163.0 ft; Fig. 7; Table 20). An interval of uncertainty (no samples available; see Table 2) of about 20 ft (ca. 6 m) exists below and above the documented range of this new species, which could therefore occur over a maximum thickness of 80.6 ft (ca. 24.5 m).

Age assignment. The *camilleae* subbiozone is tentatively attributed to the upper Aeronian-lowermost Telychian? because in the Baq'a-4 core hole the index species ranges in an interval situated between strata yielding graptolites firmly attributed to the *convolutus* Biozone (269.4 ft) below and to the *guerichi* Biozone (135.55 ft) above the top. Less conclusive graptolites occurring at 218.55 ft to 268.90 ft are questionably referred to the *convolutus* Biozone (Zalasiewicz et al., 2007, fig. 6). The LAD of *A. camilleae* sp. nov. is located close to but below the FAD of *Calpichitina densa* regarded as a Telychian species in Baltoscandia (see discussion below for the *macclurei* Biozone).

3.6. *The Angochitina macclurei Biozone*

Definition. This biozone as originally defined by Paris et al. (1995) corresponded to the acme-range biozone of *Angochitina macclurei* Paris and Al-Hajri, 1995. In its present usage, the *macclurei* Biozone corresponds to the interval-range biozone between the FAD of the index species and the LAD of *Armoricochitina crassicarinata* sp. nov. (Fig. 8; Table 21). This fits quite well with the total-range of *A. macclurei*. Two morphotypes are recorded in the samples from the Baq'a-3 and Baq'a-4 core holes. They are regarded as remaining within the intraspecific variations of the index species. The first morphotype is rather short (total length ranging approximately from 220 μm to 280 μm , and the ratio of the length of the neck to the chamber length is less than three) (e.g., Plate VII, 2–3; Plate IX, 2; Plate XI, 1; Plate XIV, 1, 5). The second morphotype, which corresponds exactly to the type material of the species, is much more slender and longer (up to 400 μm). It has a more spherical chamber and a long and narrow neck (about three times the chamber length) (e.g., Plate XII, 4–5). This morphotype is common in the Baq'a-3 well. The specimens with very rare spines on the neck are regarded as gradational between *A. hemeri* and *A. macclurei*. A biometric study would possibly reveal an evolutionary lineage within *A. macclurei* but the present samples are not suitable for such study.

Main components. A few species, e.g. *C. caputoi* (3% or less; Plate XIV, 3) and *Calpichitina* sp., already recorded in the *hemeri* Biozone are still sporadically recorded in the *macclurei* Biozone in the Baq'a-4 and Baq'a-3 core holes (Figs. 7–8). Other taxa, e.g. *Conochitina* cf. *edjelensis* (6% or less), *P. pseudoagglutinans* (Plate VII, 6), and *P. deichaii* (Plate XVI, 8), extend beyond the upper limit of the biozone as documented in the Baq'a-3 core hole (Fig. 8; Table 21). Some new species are restricted to the lower part, e.g. *Fungochitina merrelli* sp.

nov. (Plate IX, 1, 3; Plate X, 5) and *Ancyrochitina alhajrii* sp. nov. (Plate X, 2, 4), when others are restricted to the upper part of the *macclurei* Biozone (Fig. 8), e.g. *Armoricochitina crassicarinata* sp. nov. (Plate XI, 2; Plate XII, 2, 6; Plate XIV, 7) and *Armoricochitina?* sp. (Plate XIII, 2). Except for *A. alhajrii* sp. nov. and *A. crassicarinata* sp. nov., which represent respectively 27% to 42%, and 1% to 24% of the identified taxa in the corresponding samples, the relative abundance of the other new species is less than 10%. *Calpichitina densa* (Plate VIII, 7; Plate XII, 8; Plate XIII, 3) ranges virtually through the entire *macclurei* Biozone and can be used as an alternative species for identifying this biozone. *C. densa*, however, has a very low relative abundance ranging from 1% to 4% (Figs. 7–8). In the Baq'a-4 core hole, *Plectochitina alisawyahensis* sp. nov. has its FAD at 140.6 ft, exactly in the same sample as *A. macclurei*. The relative frequencies of this polymorphic species fluctuate greatly. The species is separated here from other very similar but ill-defined *Plectochitina* species, e.g., *P. saharica* (Taugourdeau, 1962) and *P. combazii* Cramer, 1967 because *P. alisawyahensis* sp. nov. has wider processes (see discussion below, in the Systematic section). The latter includes individuals with two (e.g., Plate IX, 4, 6; Plate XII, 7) or several sets of simple /or branched processes anastomosed at their distal extremity (e.g., Plate XV, 4–5, 8). *P. alisawyahensis* is missing in some samples (e.g., in the lower part of the Baq'a-3 core hole) but dominates the neighbouring chitinozoan assemblage (55% of the taxa recorded at 450.1 ft) (Fig. 8; Table 21). The species extends above the FAD of *A. macclurei* and occurs sporadically up to 150.4 ft depth in the Baq'a-3 core hole.

Range. In Baq'a-4, the *macclurei* Biozone occurs from 140.6 ft to the highest investigated sample at 40.1 ft. Due to the sampling intervals, there is an uncertainty interval of less than 22.4 ft (6.8 m) on the FAD of the index species. In the Baq'a-3 core hole, *A. macclurei* occurs from the deepest processed sample at 518.3 ft up to 330.4 ft, i.e. in an interval of at least

187.9 ft thick (ca. 57 m) (Figs. 8 and 9). The last well-represented *A. macclurei* specimens are observed at 306.0 ft (Fig. 8; the specimen recorded at 250.5 ft is regarded as questionable).

Consequently, according to the definition adopted here the *macclurei* Biozone is very close to the total-range of the eponymous species. Moreover, *A. macclurei* is usually dominant in this biozone (relative abundances close to 50% or even exceeding 50% in the upper part of the biozone; see Fig. 8). This acme-interval was also documented in the TINT-2 well (Paris et al., 1995), where the species was originally recorded under the provisional name “*Sphaerochitina longicollis* form A” by Paris (1992) (see synonymy in Paris and Al-Hajri, 1995).

Age assignment. The recent investigations on the graptolites from the Baq’a-3 and Baq’a-4 core holes (Zalasiewicz et al., 2007) provide direct ties with the early Telychian *guerichi* and possibly *turriculatus* graptolite biozones (Fig. 9). The *guerichi* Biozone is documented in the Baq’a-4 well from 135.55 ft to 37.1 ft, and from 500.50 ft to 454.40 ft in the Baq’a-3 well, where the *turriculatus* Biozone *sensu lato* is identified at 367 ft and from 303 ft to 336 ft (Zalasiewicz et al., 2007, fig. 6). This means that the entire *macclurei* Biozone occurs within the lower Telychian. Until the recent investigations on the graptolites from the Qusaiba type area in northern Central Saudi Arabia, the *macclurei* Biozone was tentatively referred to the middle part of the Telychian (Paris et al., 1995, fig. 4). *A. macclurei* was restricted to the northern Gondwana regions and the previous correlation was therefore based on the range of accompanying species such as *Calpichitina densa* whose age assignment is better constrained in Baltoscandia (Laufeld, 1974; Nestor, 1994). In spite of the compression that greatly modifies the silhouette of all the individuals available in the three studied core holes, the very distinctive chain-forming Desmochitinae from the Baq’a-4 (120.1 to 40.1 ft; see Fig. 7; Table 20) and from the Baq’a-3 core holes (518.3 ft to 306.0 ft; Fig. 8; Table 21) are here assigned to *Calpichitina densa* (Plate VIII, 7; Plate XII, 8; Plate XIII, 3). Among the closest

related species is *Margachitina banwyensis* Mullins, 2000. The northern Gondwana specimens have no evidence of a peduncle (see Plate XII, 8b) as one would expect in the lineage of the earliest *Margachitina*. The present form has been provisionally identified in Libya as ?*Margachitina leonensis* (Hill et al., 1985, pl. 13, figs. 9a-b) or as *M. margaritana* (Paris, 1988a). *C. densa*, whose total range is virtually identical to that of *A. macclurei* in the Baq'a-4 and Baq'a-3 core holes, is a well-known species in the Telychian of Baltoscandia (see references in Nestor, 1994; Verniers et al., 1995; Loydell et al., 2003, 2010) and in the U.K. (see references in Mullins and Loydell, 2001).

3.7. *The Fungochitina merrelli subbiozone*

Definition. This local subbiozone corresponds to the interval-range of *Fungochitina merrelli* sp. nov. between its FAD and the FAD of *A. crassicarinata* sp. nov., as documented in the Baq'a-3 and Baq'a-4 wells (Figs. 7–8). *Fungochitina merrelli* sp. nov. is a small chitinozoan (total vesicle length ranging approximately from 100 to 120 micrometers) with a conical chamber terminated by a short neck (chamber and neck lengths are nearly equal) (Plate IX, 1, 3; Plate X, 5). Densely distributed slender spines occasionally with *lambda*-shaped proximal ends (Plate X, 5b) cover the chamber. The very low frequency of *F. merrelli* sp. nov. in the Baq'a 3 core hole (<1%) at 408.7 ft, i.e. at the base of the succeeding *crassicarinata* subbiozone) suggests that the *merrelli* interval-range subbiozone, as defined here, corresponds very closely to the total range of the index species.

Main components. Several species among the taxa recorded in the *macclurei* Biozone are also represented in this subbiozone (see Figs. 7–8 for their respective relative frequencies). A few taxa are long ranging species with moderate to low relative frequencies, e.g. *P. deichaii*

and *C. caputoi* (Fig. 8; Table 21). Some other species, such as *P. alisawyahensis* sp. nov. (dominant species with a relative frequency of 55% at the base of the subbiozone), *A. alhajrii* sp. nov. (also well-represented in the biozone; Fig. 8) and *C. densa*, have their FAD close to, or at the base of the *merrelli* local subbiozone and extend above its upper limit. When compared to the abundance of *A. alhajrii* sp. nov. in the *merrelli* local subbiozone in the Baq'a-3 core hole (relative frequencies ranging from 42% in the uppermost *merrelli* subbiozone to 27% just above, at 388 ft), its absence in the Baq'a-4 well is puzzling. This absence of record may be due to the fact that only the lower part of the *merrelli* local subbiozone is documented in Baq'a-4. In that case the range of *F. merrelli* is much shorter in Baq'a-3 if one excludes the questionable individuals recorded at 518.3 ft in Baq'a-3.

Range. In Baq'a-4, *F. merrelli* sp. nov. is recorded at 120.1 ft and at 40.1 ft (highest processed sample in this shallow core). Its total range is therefore present in at least of 80 ft (24.3 m) with an uncertainty of about 20.5 ft (6.2 m) concerning the FAD of the index species, due to the sample spacing (Fig. 7; Table 20). The absence of *A. alhajrii* sp. nov. and of *A. crassicarinata* sp. nov. in the highest investigated sample in the Baq'a-4 core hole, suggests that the top of the *merrelli* subbiozone is not reached at 40.1 ft in this shallow well (see discussion above).

In Baq'a-3, *F. merrelli* is recorded from 450.1 ft to 408.7 ft (in this last occurrence, however, its relative abundance is less than 1%). Thus, its total range is at least of 41.4 ft (12.6 m), with an uncertainty close to 20 ft, concerning respectively its FAD and its LAD, due to the sample spacing (Fig. 8; Table 21).

Age assignment. *F. merrelli* sp. nov. does not provide independent age control. Based on the

associated graptolites of the *guerichi* Biozone recorded in wells Baq'a-4 (135.55 ft to 37.1 ft) and Baq'a-3 (500.5 ft to 454 ft) (Zalasiewicz et al., 2007, figs. 6 and 5 respectively) the *merrelli* subbiozone fits almost perfectly within this lowermost Telychian graptolite biozone (Fig. 9).

3.8. *The Armoricochitina crassicarinata subbiozone*

Definition. This local subbiozone corresponds to the total range of *Armoricochitina crassicarinata* sp. nov., as documented in the Baq'a-3 core hole (Fig. 8; Table 21). *A. crassicarinata* sp. nov. is a rather small chitinozoan (the vesicle length ranges around 120 μm). *A. crassicarinata* sp. nov. was reported in core 1 from well ISWH EW-9 with a provisional name *Armoricochitina?* sp. nov. A (see Paris, 1993, pl. 2: figs. 4-5).

Main components

Most of the species recorded in the *macclurei* Biozone, e.g. *P. deichaii*, *C. densa*, *P. alisawyahensis* sp. nov. with the exception of *F. merrelli* sp. nov. are represented in this subbiozone. Other taxa have their FAD within the *crassicarinata* subbiozone, e.g. *Tanuchitina obtusa* (Plate XIII, 4–5; Plate XVI, 6; Plate XVIII, 6) and representatives of the *Ancyrochitina aculeata* complex (Plate XII, 1; Plate XIII, 8; Plate XIV, 2). It must be noted that the lowest record of *Cutichitina minivelata* sp. nov. in the Baq'a-3 core hole does not represent the FAD of this species, which already occurs sporadically, but with higher relative abundances in older strata in the Qusaiba-1 core hole (Fig. 6; Table 19). Specimens resembling *Cingulochitina* species at 350.1 ft (Plate XIII, 2) and at 330.4 ft are tentatively identified *Armoricochitina?* sp. (1% to 3% of the recorded individuals) (Fig. 8; Table 21).

Range. The *crassicarinata* local subbiozone is documented from 408.7 ft to 330.4 ft in the Baq'a-3, i.e. over 78.3 ft (ca. 24 m) of depth in the borehole (Fig. 8; Table 21). Due to the spacing of the samples, an interval of uncertainty of 23 ft (7 m) exists both for the FAD and LAD of *A. crassicarinata* and thus this subbiozone could range over at maximum of 125.7 ft (ca. 38 m) in this core hole.

If one accepts the synonymy proposed here between *A. crassicarinata* sp. nov. and *Armoricochitina?* n. sp. A in Paris (1993), *A. crassicarinata* ranges from 3517.4-3623.6 ft (1070-1072 m; cuttings) to 3609.1 ft (1098 m; lowest processed sample in core 1) in well ISWH EW-9 (fig. 2 in Paris, 1993). Consequently, *A. crassicarinata* ranges at least over 91.7 ft (28 m) in the ISWH EW-9 borehole, where its total range is probably closer to 131 ft (ca. 40 m), if one considers the position of its acme in Baq'a-3 and in ISWH EW-9.

Age assignment. *A. crassicarinata* is a new species and therefore, on itself, it does not provide an independent age control. Its location in the upper part of the *macclurei* regional Biozone supports an early Telychian age (see discussion above for the *macclurei* Biozone). At least the middle part of the *crassicarinata* subbiozone is tied to the *turriculatus* s.l. graptolite Biozone identified at 367 ft in the Baq'a-3 core hole (Zalasiewicz et al., 2007, fig. 5). Early Telychian graptolites (*turriculatus* s.l. Biozone) are recorded in the upper part of the *crassicarinata* subbiozone at 336 ft in the Baq'a-3 core hole. It must be noted that no typical *A. macclurei* were recorded in well ISWH EW-9, and thus the uppermost range of *A. crassicarinata* could extend slightly above the LAD of *A. macclurei* in this latter well.

3.9. *The Tanuchitina obtusa Biozone*

Definition. This regional biozone corresponds to the interval-range biozone between the LAD

of *Armoricochitina crassicarinata* sp. nov. (i.e., equivalent to the FAD of *Plectochitina jacquelineae* sp. nov.) and the FAD of *Euconochitina silurica* (Taugourdeau, 1963). It must be noted that *T. obtusa* has its FAD within the upper part of the *macclurei* Biozone.

Considering the isolated record of a single specimen at 150.4 ft, the LAD of *T. obtusa* is within the succeeding *silurica* regional Biozone.

Main components. *Tanuchitina obtusa* (Taugourdeau and de Jekhowsky, 1960), the index species of this regional biozone, is a long chitinozoan (vesicle length ranging usually from 350 μm to 450 μm) with gently tapering straight flanks (Plate XIII, 4–5; Plate XV, 2; Plate XVI, 6; Plate XVIII, 6). It has sporadic occurrences and the recorded relative abundances do not exceed 10% (Fig. 8). Among the most common species is *Plectochitina longicornis* (Taugourdeau and de Jekhowsky, 1960) (Plate XVI, 7), which may represent up to 20% of the recorded species (Fig. 8; Table 21). This species has been previously reported from well ISWH EW-9 under the name *P. paraguayensis* “form B”. It was recorded in cuttings from 3247 ft to 3594.9 ft (990 m to 1096 m), but not from core 1 at 3586.7 ft to 3601.4 ft (1093.5 m to 1098 m), so caving can be suspected for occurrence in the deeper cutting samples. In the discussion of *P. paraguayensis* Wood and Miller, 1991, Paris (1993) noted the great similarity between his “form B”, *P. longicornis* and *P. nodosa* (the latter is herein regarded as a synonym of *P. longicornis*) but he did not assign this “form B” to *P. longicornis* for stratigraphical reasons. In Algeria, the type material of the two species was from cuttings located above an upper Silurian core sample. Recent investigations (F. Paris unpublished) have not recorded *P. longicornis* or any morphologically similar forms in the late Silurian or in the Early Devonian of Algeria. Because a few sample mixing is proved in some of the older Saharan studies, a wrong location is also suspected for the type sample of *P. longicornis*, which may as well be of early Silurian age. In spite it is a *nomen dubium* the species name

longicornis is however used here. *Plectochitina alisawyahensis* sp. nov. is still present in this biozone but its relative abundance is much lower (4 % or less) than in the underlying *macclurei* Biozone. The long ranging *P. deichaii* is again fairly abundant (15% at 250.5 ft) as well as other taxa, with sporadic occurrences, e.g. *C. minivelata* sp. nov. or *A. gr. aculeata*. Spectacular forms with an unusually well-developed membrane joining the proximal part of the broken processes are tentatively identified as *P. cf. alisawyahensis* (Plate XV, 6) and as *Anthochitina?* sp. A new species, *Plectochitina jacquelineae* sp. nov. is restricted to the sample at 306.0 ft (Fig. 8; Table 21), i.e. at the base of the *obtusa* Biozone as defined above. Other interesting species are recorded in the biozone, e.g. *Plectochitina lucasi* sp. nov. (Plate XV, 3, 7), which is dominant in the lower part of the *obtusa* Biozone (see below the definition of the *lucasi* subbiozone) and *Armoricochitina gengi* sp. nov. (Plate XV, 1), which represents only 3% of the chitinozoans recorded at 250.5 ft (Fig. 8; Table 21). *A. gengi* sp. nov. was reported as *Armoricochitina* n. sp. aff. *panzuda* (see Paris, 1993; pl. 2, fig. 3a-b) in cuttings from well ISWH EW-9. In this well, it ranges from 3247 ft to 3568.6 ft (990 m to 1088 m) (the deepest records were possibly the result of caving). The striking occurrence of a large number (39% of the recorded chitinozoans at 206.9 ft; Fig. 8; Table 21) of *Cyathochitina neolatipatagium* sp. nov. in the upper part of the *obtusa* Biozone must be noted. A similar “bloom-like” event of this species was recorded in Qusaiba-1 within a short interval of less than 1.5 m thick in the upper part of the *hemeri* regional Biozone. Such bio-events are puzzling because they have no clear biostratigraphical explanation (Männil, 1971). They likely result from recurrent peculiar environmental conditions, which were specifically favourable for the *Cyathochitina* producers. A few *C. neolatipatagium* sp. nov. occur in core 1 of well ISWH EW-9 (not listed in Paris, 1993).

Range. The interval-range of *T. obtusa* extends for 99.1 ft depth (ca. 30 m) from 306.0 ft to

206.9 ft in the Baq'a-3 shallow core (Figs. 8–9). Due to the sample spacing an interval of uncertainty respectively of ca. 20.3 ft and 14.4 ft (6.2 and 4.4 m) exists on the lower and upper limit of the biozone. In the ISWH EW-9 well, the *obtusa* Biozone occurs over 164 ft (ca. 50 m), and possibly more as the youngest cutting sample at 3254.1–3287 ft (990–1000 m) still contains *A. gengi* sp. nov. but not *Euconochitina silurica*, which is the index species of the succeeding biozone. In the ISWH EW-9 well, the *obtusa* Biozone as defined here corresponds to “Assemblages 3 and 4” of Paris (1993, fig. 2), whereas “Assemblages 1 and 2” correspond to the *crassicarinata* subbiozone in the terminal part of the *macclurei* regional biozone (Fig. 9).

Age assignment. None of the species recorded in the *obtusa* Biozone provide accurate chronostratigraphical information. The absence of early Sheinwoodian chitinozoans, such as *Margachitina margaritana*, suggests that the *obtusa* Biozone still belongs to the Telychian, and probably to the mid to late Telychian, as graptolites (*turriculatus* s.l. Biozone) are still present at 303 ft. The graptolites, and especially the retiolitids recovered in the palynological residue from 229.7 ft in Baq'a-3 should give a better tie with the standard graptolite zonation of the Telychian. The *obtusa* Biozone is at present tentatively correlated with levels within the *griestoniensis* to *spiralis* graptolite zones.

3.10. The *Plectochitina jacquelineae* sp. nov. subbiozone

Definition. This local subbiozone corresponds to the total range of *Plectochitina jacquelineae* sp. nov. The index species is only reported at 306.0 ft, in the sample yielding the last abundant *A. macclurei*. This is also the lowest available sample immediately above the top of the *macclurei* interval-range Biozone. In spite of the fact that it is restricted to a single sample

in the Baq'a-3 core hole (Fig. 8; Table 21), this subbiozone is defined because *Plectochitina jacquelineae* sp. nov. has a distinctive morphology and is easy to identify, even on poorly preserved specimens (Plate XIV, 4, 6).

Main components. *Plectochitina jacquelineae* sp. nov. occurs with all the major components recovered from the upper part of the *macclurei* Biozone, i.e. the index species itself, *A. gr. aculeata*, *T. obtusa*, *P. alisawyahensis* sp. nov., *C. minivelata* sp. nov. (dominant in the assemblage with 37% of the recorded individuals) and the youngest recorded *C. densa* and *C. caputoi* (Fig. 8; Table 21).

Range. During the present study, *Plectochitina jacquelineae* sp. nov. has been recorded only from a single sample at depth 306.0 ft in the Baq'a-3 core hole. Due to the spacing of the available samples, an uncertainty of ca. 23.1 ft (7 m) exists theoretically on its real LAD and FAD in Baq'a-3 (Fig. 8; Table 21). According to the synonymies proposed here, *Plectochitina jacquelineae* sp. nov. is also represented in the Qusaiba Member of the ISWH EW-9 well (Paris, 1993) and of the Tabuk and Qasim areas (McClure, 1988).

Age assignment. *Plectochitina jacquelineae* sp. nov. is a new species, and thus cannot be used for independent dating of this subbiozone. In the Baq'a-3 core hole, however, *Plectochitina jacquelineae* sp. nov. occurs with graptolites of the *turriculatus* s. l. Biozone indicating an early Telychian age for this subbiozone. A similar age is proposed for the corresponding strata in the ISWH EW-9 well.

Fairly closely related forms, such as *Anthochitina primula* Nestor, 1994, or individuals identified as *Ancyrochitina ansarviensis* Laufeld (in Nestor, 1994, pl. 1, fig. 7) are known in

the Adavere regional stage in the Baltic area, i.e., in the upper Telychian according to the correlation proposed by Nestor (1994) and improved by comparisons between graptolites and chitinozoan biozonations (Loydell et al., 1998, 2003, 2010).

3.11. *The Plectochitina lucasi* sp. nov. subbiozone

Definition. The subbiozone corresponds to the total range biozone of *Plectochitina lucasi* sp. nov. The index species (Plate XV, 3, 7) is the dominant species in the lower part of the *obtusa* Biozone (e.g., 63% of the recorded individuals at 271.8 ft; see Fig. 8). This new species (see Systematic section) has a distinctive silhouette. The processes are hollow and display *lambda* or multi-rooted proximal ends (Plate XV, 7b). This new species was reported in well ISWH EW-9 in open nomenclature as “*Ancyrochitina* n. sp. B” (see Paris, 1993; pl. 2, figs. 1-2).

Main components. The accompanying species are the long ranging *P. deichaii*, and shorter ranging species, e.g. *Plectochitina alisawyahensis* sp. nov., *C. minivelata* sp. nov., *A. gr. aculeata*, and *T. obtusa* (see Fig. 8 and description of the *obtusa* Biozone above).

Range. *P. lucasi* sp. nov. occurs from 289.1 ft to 250.5 ft, i.e. at least over 38.6 ft (11.7 m). Due to the sample spacing, an interval of uncertainty of respectively 16.9 ft (5.15 m) and 20.8 ft (6.3 m) exists for the base and the top of the *lucasi* subbiozone in the Baq’a-3 shallow core (Fig. 8; Table 21).

If one accepts the synonymy proposed here between *P. lucasi* sp. nov. and “*Ancyrochitina* n. sp. B” in Paris (1993), it ranges in the ISWH EW-9 well in cuttings samples from 3470.2 ft to 3588.3 ft (1058 to 1094 m). Thus, its range is over 118 ft (36 m; see Fig. 9), and likely less

because the deepest individuals could be caved, as they occur within the upper range of *A. crassicarinata* in “Assemblage 2” of Paris (1993). The absence of *P. lucasi* sp. nov. in core 1 (1993.5 to 1098 m) in the ISWH EW-9 well confirms this interpretation.

Age assignment. No graptolites are recorded in the samples yielding *P. lucasi* sp. nov. Moreover, the chitinozoan species recorded in the *lucasi* subbiozone do not allow direct correlation with the early Silurian chronostratigraphy. Thus the same arguments as for the *obtusa* Biozone are used for determining the age of the *lucasi* subbiozone. The absence of *Margachitina margaritana*, a widespread early Sheinwoodian chitinozoan, is regarded as an argument for keeping the *lucasi* subbiozone in the Telychian.

3.12. *The Euconochitina silurica* Biozone

Definition. This biozone corresponds to the total range biozone of *Euconochitina silurica* (Taugourdeau, 1963). The LAD of the index species is not documented in the processed material (no sample available above 130 ft in the Baq'a-3 core hole). Taugourdeau (1963) defined *E. silurica* in a core sample from the eastern part of the Illizi Basin, SE Algerian Sahara (sample at 1445 m depth in well Zr. 1). The original name was *Conochitina oelandica* subsp. *silurica*. This subspecies is raised here to species rank because of its discriminating characters. *E. silurica* is a very small chitinozoan (Plate XVIII, 3–4), which has a total length ranging around 90-110 μm in the investigated samples. It displays a conical chamber with a rounded margin. The sub-cylindrical neck may represent half to one third of the vesicle length. The vesicle wall is smooth; a small scar occurs on the apex of the vesicle (Plate XVIII, 4).

Main components. Several taxa present in the underlying biozones range into this biozone (Fig. 8; Table 21). They include the highest occurring specimens of *P. deichaii*, as well as representatives of *P. alisawyahensis* sp. nov. The latter may be fairly abundant (e.g., 18% of the recorded specimens at 150.4 ft), *Calpichitina* cf. *acollaris* (Plate XVII, 6, 8) and *C. minivelata* sp. nov., which has a surprisingly high relative frequency (62%) at 192.5 ft, when *E. silurica* has its FAD (Fig. 8; Table 21). Other species range into the *silurica* Biozone. *Armoricochitina gengi* sp. nov. (Plate XVII, 1–2) dominates the assemblage (42% of the recorded individuals) at 150.4 ft, whereas another form, tentatively identified as *Fungochitina?* sp. (Plate XVII, 3–5), is the most abundant form (51%) at 170.9 ft (Fig. 8; Table 21). *Fungochitina?* sp. has a fungiform chamber, which may be variously modified during lateral compression of the vesicle (e.g., Plate XVII, 4). The walls bear granules to small spines. The most striking element, however, is the very short and irregular rim-like structure (remains of a carina?) running around its rounded margin. To some extent, such structure recalls the short carina of *Anthochitina jawfensis* Al-Hajri and Paris, 1998 from the Sharawra Member of the Qalibah Formation. The preservation of this possible carina is too poor and the form is therefore provisionally referred to *Fungochitina*, rather than to *Anthochitina*. *E. silurica* dominates the highest investigated chitinozoan assemblage at 130 ft (79% of the recorded individuals), where it coexists with a form tentatively referred to *Plectochitina* cf. *lucasi* sp. nov. The specimens recorded at 130 ft differ slightly from the population of *P. lucasi* sp. nov. observed in the preceding *obtusa* Biozone (see discussion below in the Systematic section). *P.* cf. *lucasi* sp. nov. (Plate XVIII, 1b, 2b) possesses also a conical chamber and a very long neck flaring close to the aperture but the walls are covered with randomly distributed granules and the processes are shorter than in the typical populations of *P. lucasi* sp. nov.

Range. The *silurica* regional Biozone occurs from 192.5 to 130.0 ft, in the upper 62.5 ft (19 m) of the Baq'a-3 core hole. This interval thickness must be regarded as a minimum as the relative abundance of the index species is very high in the last processed sample and the biozone most likely extends into younger strata not investigated here. The stratigraphic range of the index species is unknown in its type locality in Algeria, which is based on an isolated sample.

Age assignment. The *silurica* regional Biozone, like the preceding ones, does not contain chitinozoan species permitting an independent age assignment. Again, the absence of *Margachitina margaritana*, which has a FAD that is well-constrained in British sections (Mullins and Loydell, 2001) and in Baltoscandian sections (Nestor, 1994; Loydell et al., 2003, 2010), is used here for tentatively dating the *silurica* Biozone as pre-Sheinwoodian. No graptolite remains have been observed from the samples yielding *E. silurica*. This may result from too shallow-water environments in the uppermost part of the Qusaiba Member as indicated by the abundance of eurypterid remains in the organic residue (Silurian eurypterids are usually regarded as near-shore organisms). The occurrence of retiolitid graptolites just below the base of the *silurica* Biozone is compatible with a late Telychian age for this biozone (possibly within the time interval corresponding to the *spiralis* to *centrifugus* graptolite zones). The *silurica* Biozone is here regarded as a faunal indicator of the upper part of the Qusaiba Member, close to its boundary with the Sharawra Member.

4. Chronostratigraphy of the Qusaiba Member

One informal assemblage (“Assemblage 1” in Paris et al., this volume) and six chitinozoan

biozones have been identified in the investigated samples from the Qusaiba-1, Baq'a-4 and Baq'a-3 core holes. In ascending order are the *qusaibaensis* (*pro parte*), *alargada*, *hemeri*, *macclurei*, *obtusa* and *silurica* biozones. These biozones are considered of regional value, i.e. usable in the northern Gondwana regions (north and west Africa, southern parts of Europe, the Arabian Plate and western Iran). In addition, five subbiozones of more local value (Arabian Plate or beyond) are proposed (Fig. 9). One characterises the upper part of the *hemeri* Biozone (the *camilleae* subbiozone). Two other biostratigraphic subdivisions (the *merrelli* and the *crassicarinata* subbiozones) are part of the *macclurei* Biozone. The two remaining (*jacquelineae* and *lucasi* subbiozones) occur within the *obtusa* Biozone.

The chitinozoans recorded in the lowermost part of the Qusaiba Member in the Qusaiba-1 core hole, permit identification of a distinctive early Rhuddanian chitinozoan assemblage ("Assemblage 1" in Paris et al., this volume). No formal biozone name is proposed for this assemblage located immediately above the top of the Sarah Formation (Figs. 3 and 6) because apart from *B. pseudarabiensis* it does not contain key chitinozoan species of the lower Llandovery chitinozoan biozonation. Nevertheless, based on similar chitinozoan assemblages coexisting with early Rhuddanian graptolites in other northern Gondwana localities, the association with dominant *C. caputoi* and *B. pseudarabiensis* is considered diagnostic of the basalmost Silurian (see discussion in Paris et al., this volume). Because the immediately overlying strata yield chitinozoans of the *qusaibaensis* Biozone associated with graptolites of the *convolutus* graptolite Biozone, a significant hiatus (most of the Rhuddanian and Aeronian *pro parte*) is recognized in the lower part of the Qusaiba Member (core 27 at 254.5 ft; Fig. 6).

Whenever the sedimentary record is complete, the *qusaibaensis* interval-range Biozone originates in the upper Rhuddanian and ends in the early mid-Aeronian. In the Qusaiba-1

shallow core, only the upper part of the *qusaibaensis* Biozone corresponding to the *convolutus* graptolite Biozone *pro parte* (Zalasiewicz et al., 2007) is represented in cores 27 (upper part) and 26. This upper part of the *qusaibaensis* is well characterized by *Muscochitina olivieri* sp. nov. a taxon also recovered in core 20 in the TINT-2 well and in core 17 of the UDYN-1 well.

In the Qusaiba-1 core hole, the *alargada* interval-range Biozone reported from cores 25 to 22 is assigned to the middle Aeronian, based on the combined occurrence of the chitinozoans with graptolites of the lower part of the *convolutus* Biozone (Fig. 9).

The *hemeri* interval-range Biozone is documented in the upper part of the Qusaiba-1 and in the lower part of the Baq'a-4 core holes (Paris, 2003, 2005). This biozone was identified also in deep core samples from eastern Central Saudi Arabia (Paris et al., 1995), e.g. core 17 from UDYN-1 (Paris, 1991) and cores 17-20 from TINT-2 (Paris, 1992). Graptolites of the *convolutus* Biozone are associated with the chitinozoans of the *hemeri* Biozone, both in the Qusaiba-1 (cores 22 to 14) and in the Baq'a-4 (cores 31 to 19) wells. These graptolites provide a precise correlation with the middle part of the Aeronian (Zalasiewicz et al., 2007). The *camilleae* sp. nov. total-range subbiozone is identified in the upper part of the *hemeri* Biozone, cores 23 to 19 (i.e., middle part of the Baq'a-4 core hole). The mid-Aeronian age assignment of the *camilleae* subbiozone is based on its direct calibration by graptolites of the *convolutus* Biozone (Fig. 9).

The *macclurei* interval-range biozone is identified in the upper part of the Baq'a-4 and in the lower part of the Baq'a-3 shallow cores. The early Telychian graptolites (Zalasiewicz et al., 2007) occurring with the index species in the two shallow cores provide a precise and independent calibration of this biozone. Its lower part is represented in cores 17 to 7 (i.e. from

140.6 to 40.1 ft) of the Baq'a-4 well, where the chitinozoans of the *macclurei* Biozone occur with graptolites of the *guerichi* Biozone. The middle and upper part of the biozone is documented from the lower part (cores 56 to 36, i.e. from 518.3 ft to 330.4 ft) of the Baq'a-3 core hole. In this well, the chitinozoans are associated with graptolites of the *turriculatus* s.l. Biozone in core 40 (367 ft), and in cores 34 and 36 of early Telychian age (Fig. 9). The *macclurei* Biozone was originally defined in core 16 of TINT-2 well and tentatively attributed to the late Telychian (Paris et al., 1995). The present data indicate that this previous dating must be corrected. The *macclurei* Biozone range is restricted to the lower Telychian. The *merrelli* sp. nov. total-range subbiozone is identified in cores 15 to 7 from the uppermost part of the Baq'a-4 well and from cores 49 and 47 from the lower part of the Baq'a-3 well. This subbiozone, which represents the lower part of the *macclurei* Biozone, has been documented in other Saudi Arabian wells. It is assigned to the early Telychian as it is bracketed by graptolites of the *guerichi* and *turriculatus* biozones (Fig. 9). The *crassicarinata* sp. nov. total-range subbiozone is identified in cores 45 to 36 (from 408.7 ft to 330.4 ft) from the middle part of the Baq'a-3 core hole. This subbiozone is well-represented in the ISWH EW-9 well (core 1, and cuttings corresponding to "Assemblage 2" in Paris, 1993). The subbiozone is most likely present in the upper part of core 16 from the TINT-2 well after a reappraisal of the less well-preserved individuals, unnamed in Paris (1992). The *crassicarinata* subbiozone is assigned to the early Telychian based on a direct graptolite calibration in the Baq'a-3 core hole where the *crassicarinata* subbiozone occurs with graptolites (*M. e.g. gr. marri* at 367 ft and *S. becki* at 336 ft). Zalasiewicz et al. (2007, fig. 5) referred these graptolites to the *turriculatus* s.l. Biozone (Fig. 9).

The *obtusa* interval-range Biozone is identified in the upper part of the Baq'a-3 well (cores 34 to 22, i.e. from 306.0 ft to 206.9 ft), and in core 1 and cuttings samples from 3293.1 ft (1004

m) to 3509.6 ft (1070 m) from ISWH EW-9. In terms of graptolite zones, no direct calibration of the *obtusa* Biozone is presently available in Saudi Arabia or in other northern Gondwana regions (e.g. Algeria, Spain). Tentatively, a mid- to late Telychian age assignment is proposed here based on indirect evidence, as the *obtusa* Biozone is recorded above early Telychian strata and does not contain the Sheinwoodian chitinozoans known in other northern Gondwana localities (Fig. 9).

The *Plectochitina jacquelineae* sp. nov. subbiozone is restricted to core 34 (306.0 ft) in the Baq'a-3 core hole. This taxon ranges briefly in cuttings from 3299.7 ft to 3509.6 ft (1006 to 1070 m) and in core 1 (at 1093.5 m, i.e. 3586.7 ft) in the ISWH EW-9 well. Based on graptolite evidences (graptolites of the *turriculatus* s.l. Biozone recorded up to 303 ft in Baq'a-3; Zalasiewicz et al., 2007) the subbiozone also can be attributed to the lower Telychian. Core 34 from the Baq'a-3 well and the cuttings from the ISWH EW-9 are therefore tentatively assigned to the lower Telychian.

The *lucasi* sp. nov. total-range subbiozone occurs from core 32 to core 27 (from 289.1 ft to 229.7 ft) in the middle part of Baq'a-3. The *lucasi* subbiozone is also documented in ISWH EW-9 well where the index species occurs in "Assemblage 3" *sensu* Paris (1993) in cuttings from 3470.5 ft to 3509.6 ft (1058 to 1070 m). In the ISWH EW-9 well the specimens recorded below in the borehole are possibly caved. The *lucasi* subbiozone is tentatively attributed to the middle and/or upper Telychian as it occurs just above samples yielding graptolites of the *turriculatus* s.l. Biozone (Fig. 9).

The *silurica* total range Biozone is identified in cores 21 to 14 from the uppermost part (192.5 ft to 130.0 ft) of the Baq'a-3 well. Its upper part is not documented in this shallow core (no samples processed above core 14). The *silurica* Biozone is known in other northern

Gondwana regions, e.g. in SE Algeria. The shallow environments of the Sharawra Member, which extends above core 14 in the Baq'a-3 well, seem unfavourable for graptolites.

Therefore, this fossil group will be of no help for dating the upper part of the *silurica* Biozone. This biozone is tentatively attributed to the late Telychian (Fig. 9) because no typical early Sheinwoodian chitinozoans, known to occur elsewhere in the Sharawra Member (Al-Hajri and Paris, 1998), are observed in this biozone.

5. Qusaiba environments and chitinozoan taphonomy

The abundance of the recorded chitinozoans in each sample of the three investigated wells has been collated with the lithology of the processed material (Tables 1–3) in order to depict possible relationships between the lithology and the abundance of the chitinozoans. The lithology is fairly constant through the investigated part of the Qusaiba Member dominated by greenish to grey shale. With the exception of the carbonaceous shale at 254.8 ft and of a thin sandy bed (254.5 ft to 253.5 ft) in the Qusaiba-1 core hole, only minor lithological variations are noticed, especially increases of the silt fractions (e.g., at 330.4 ft and 306.0 ft in Baq'a-3, or at 60.1 ft and 40.1 ft in Baq'a-4) or the occurrence of silty to fine sandy laminae (e.g., at 132.05 ft in Qusaiba-1, at 130.0 ft in Baq'a-3, and at 269.0 ft or 240.7 ft in Baq'a-4). The most significant increase of the grain size is noted in core 14 (130.0 ft) in Baq'a-3. There is not an obvious relation between the grain size or the colour of the sediment when compared to the abundance of the chitinozoans (expressed in specimens per gram of rock). One would expect to have the highest abundances in the shaly facies. The highest recorded values are in core 14 from Qusaiba-1, respectively at 140.1 ft in the grey greenish shale (3920 chitinozoans per gram of rock) and at 136.5 ft, in the grey greenish siltstone (3080 chitinozoans per gram

of rock). In the latter well, the most evident trend is an increase in the chitinozoan abundances through time, independently of the colour of the sediment. This high chitinozoan production drops significantly in the uppermost part of the well (core 14), in more silty deposits (at 133.45 ft) or deposits with sandy laminae (132.05 ft). In this core hole, eurypterid fragments occur exclusively in these two samples and a temporary shallowing is interpreted. A similar, but more conspicuous and sustained trend is also recorded in the upper part of the Baq'a-3 core hole. In this well, a correlation between a lowering of the chitinozoan abundances and the occurrence of eurypterid remains is also noticed (Table 3). A shallowing trend announcing the nearshore environments of the overlying Sharawra Member is registered in the upper part of this core hole, particularly in core 14 with the grey siltstone and sandy laminae at 130.0 ft. This sample has by far the lowest chitinozoan abundance (27 specimens per gram of rock) among the processed samples in the three investigated core holes.

To summarize, the chitinozoan abundances do not exactly reflect the lithology, as shale or siltstone samples can yield more than 9000 chitinozoans per gram of rock but conversely these two types of sediment may contain less than 100 chitinozoans per gram of rock. The most obvious limiting factor for the proliferation of most of the chitinozoan species seems to be the shallow water depositional environments. On the contrary for some species such as *C. neolatipatagium* sp. nov., these environments seem to be the most suitable (see below). The highest abundances (exceeding 9000 chitinozoans per gram of rock Table 1) are in environments leading to condensed sequences (see Melvin, this volume), e.g. the highly bioturbated carbonaceous dark shale at 254.8 ft in the Qusaiba-1 core hole (see Melvin, this volume).

Independently of the recorded chitinozoan abundances, slight discrepancies are noted in the

detailed range of some species within the Saudi Arabian Silurian sequences (Figs. 6–8). They may be partly related to sporadic occurrences and/or to the spacing of the samples. Most of these discrepancies, however, result from an environmental control on the distribution of peculiar chitinozoan species. Several taxa such as *Plectochitina alisawyahensis* sp. nov. seem to be better represented in fine-grained deposits (see Table 3 and Fig. 8), possibly due to their delicate ornamentation. Such low energy depositional settings are also required for the preservation of thin-walled delicate structures as the “sleeve” extended externally from the prosome of *A. qusaibaensis*. The fragile aggregates of crushed *Cyathochitina* recorded at 245.8 ft in the Qusaiba-1 well, and interpreted as coprolites, may have survived because they were produced in situ in the sediment (occurrence of small internal bioturbation). Other species are representative of open and deeper marine environments e.g. *Angochitina hemeri*, *Angochitina macclurei*. They are the dominating taxa in the less diversified assemblages recorded in the TINT-2 well, corresponding likely to a more distal environment setting. The slight lithological changes observed in the Baq’a-3 and Baq’a-4 core holes, however, have no real impact on the abundance of *A. macclurei* (Tables 2–3 and Figs. 7–8). Species such as *Cyathochitina neolatipatagium* sp. nov. (at 206.9 ft in the Baq’a-3 and in core 14 in Qusaiba-1 core holes) or even *Cyathochitina caputoi* have more intermittent occurrences recalling the distribution of opportunistic taxa, with bloom-like occurrences (i.e., sudden and brief proliferation, with a “Lazarus” distribution). The temporary absence of specific predators may also explain the sudden proliferation of some chitinozoan species (see discussion in Grahn and Paris, 2011). *C. neolatipatagium* sp. nov. seems dependent on the more shallow siltier environments in Qusaiba-1 (see Table 1 and Fig. 6) and Baq’a-3 (Table 3, Fig. 8). Consequently, when selecting the index species of biozones (or subbiozones) and when proposing correlation between different sections or wells, we have paid much attention to examine how far the acme biozone of a species reflects the optimal development of a species

or results from a “bloom-like” proliferation driven by local optimal environmental conditions.

6. Conclusions

The chitinozoan assemblages recovered from the Qusaiba Member of the Qalibah Formation penetrated by the Qusaiba-1, the Baq'a-4 and the Baq'a-3 core holes are extremely diverse and contain abundant and well-preserved chitinozoans. These shallow cores allowed overcoming of the effects of the deep weathering that affects the outcrop samples and precludes the use of palynomorphs for their dating. The present data permit establishing a precise biozonation for the chitinozoans in the material from the type area of the Qusaiba Member and from the neighbouring Baq'a area. The identified biozones provide excellent correlation with the subsurface sequences of the central and north-eastern parts of Saudi Arabia. Direct calibration by associated graptolites allows precise age assignment in terms of the standard graptolite biozones and of Silurian stages.

A significant hiatus representing most of the Rhuddanian and the lower part of the Aeronian is documented in the lower part of the Qusaiba Member in the Qusaiba-1 core hole. The hiatus is located above the basal part of the Qusaiba Member, which yields very abundant earliest Rhuddanian chitinozoans immediately above the last glacially related Baq'a Sand Member of the Sarah Formation (see discussion in Paris et al., this volume). This hiatus corresponds either to a gap (but no erosion or palynomorph reworking is observed) or to a highly condensed sequence as suggested by the abundant bioturbation developed in a thin sandy bed above the hiatus. The main part of the Qusaiba Member was deposited in open and low energy marine environments as demonstrated by the preservation of very delicate

structures in the chitinozoans (e.g., “sleeve” of *A. qusaibaensis*, clusters of *A. macclurei*, coprolites consisting of fragmented *Cyathochitina*).

The shallowing trend preceding the more nearshore environments of the Sharawra Member is registered by a decrease in diversity and abundance of the chitinozoans, but also by an increase in the eurypterid remains within the organic residue.

The investigations carried out on the Qusaiba Member have revealed a biodiversity of the chitinozoans through time much higher than documented previously. This allowed to describe numerous new species in the present paper. It is clear that the former published studies missed some important intervals. This was mainly due to a discontinuous and too scattered sampling of the Qusaiba sequence. One can expect now chitinozoan correlation at the scale of the Arabian palaeoplate with accuracy close to or in a few cases even more detailed than that of graptolites from this Qusaiba Member. For a long time the Saudi Arabian chitinozoan biozones suffered of a deficit of precise calibration with regard to the Silurian standard chronostratigraphy. The present study contributes significantly to improvement of the available dating in terms of Llandovery stages, thanks to the excellent ties provided by the graptolites coexisting with the chitinozoans in the upper part of the Qusaiba Member. This study indicates also that a single section is not sufficient for elaborating a regional biostratigraphic model when the geological context (major rapid transgression, or glaciation) is susceptible to generate condensed sequences or gaps of various magnitudes.

Appendix A. Main lithological and palaeontological data concerning the processed samples (Tables 1-3)

Appendix B. Systematic palaeontology (F. Paris)

The classification and the terminology proposed by Paris et al. (1999) are used for the description of the new chitinozoan species defined in the Systematic section. The measurements of the morphological parameters are expressed in micrometres (μm) and the abbreviations defined by Paris (1981) are used i.e., total length (L), chamber diameter (Dp), neck diameter (dc), collarete diameter (dcoll.), collarete length (lcoll.), neck length (lc). Biometric graphs give the size variations for each of the new species. The choice of holotypes with measurements close to the average values of the measured populations is favoured (Figs. 10–24). For the measurements, a correction of the compression of the vesicle is used depending on the importance of the flattening, e.g. coefficient of 0.8 for the chamber (usually less affected because its thicker wall near the margin) and coefficient of 0.7 for the neck and the collarete (thinner wall and thus frequently totally compressed).

The sorted specimens and the individuals observed under a Scanning Electron Microscope (SEM) are housed in the palynological collections of the Geological department of Rennes University, France (Géosciences, OSUR), with the repository numbers IGR 72251 to 72376. The coordinates of illustrated specimens are given using the England-Finder Grid.

Incertae sedis Group **Chitinozoa** Eisenack, 1931

Order **Prosomatifera** Eisenack, 1972

Family **Conochitinidae** Eisenack, 1931, emend Paris, 1981

Subfamily **Conochitinae** Paris, 1981

Genus *Conochitina* Eisenack, 1931 emend Paris et al., 1999

Type species: Conochitina claviformis Eisenack, 1931

Conochitina viiuae sp. nov. Paris (Plate I, 2; Plate II, 4–5)

v. 1985 – *Conochitina proboscifera* Eisenack, 1937; Molyneux and Paris, pl. 14, figs. 1a-b.

Derivation of the name: this species is dedicated to Viiu Nestor for her outstanding investigations on the Silurian chitinozoans from the Baltic area.

Holotype: Plate II, 5, core 26, 245.8 ft, IGR 72256 (M44/4).

Type locality: Qusaiba-1 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 26, sample from 245.8 ft, mid-Aeronian

Paratype: Plate II, 4, core 26, 245.8 ft, IGR 72256 (O44/3).

Material: 33 sorted specimens from core 26 in the Qusaiba-1 core hole but ca. 300 additional individuals in the remaining organic residue.

Diagnosis: Long and slender *Conochitina* species ($L/D_p > 6$) with an elongate claviform to sub-cylindrical chamber; long neck flaring near the aperture; vesicle walls perfectly smooth; rounded margin; convex to truncate ogival bottom with a large protruding mucron.

Description: The total length of this very long and slender chitinozoan (mean vesicle length: ca. 425 μm ; length of the holotype: 522.6 μm) shows important variations (see Table 4; Figs.

10a–b) with L ranging in the measured specimens from ca. 310 μm (collarete missing) to 686.7 μm (Plate II, 4). The narrow chamber has gently tapering straight flanks (Plate II, 4) or a drawn out claviform profile (Plate II, 5). No flexure or shoulder is present at the junction between the chamber and the long cylindrical neck, flaring near the aperture. The average ratio of the vesicle length (L) on chamber diameter (Dp) is ca. 7.6, and may exceed 10 (e.g., paratype, Plate II, 4). The length of the chamber is close to the length of the neck. A long prosome, usually with numerous septa, is located deeply in the neck. The lower part of this prosome (likely more robust) is frequently less flattened than the remaining part of the neck. The resulting differential flattening simulates a constriction in the middle part of the vesicle (Plate II, 4–5). The walls are perfectly smooth and rather thick, particularly near the margin (holotype not compressed, and thus no coefficient of correction used on Table 4). The bottom of the chamber is convex or has a truncated ogival profile due to the presence of a large circular mucron with a flat top (Plate II, 4b). The diameter of this mucron is close to half the diameter of the chamber.

Measurements (Table 4; Figs. 10a–b).

	L	Dp	Dc	Dcoll.
Holotype	522.6	(63.4)	(46.9) *37.5	(57.0) **39.9
Mean	424.5	(55.5) *44.4	(45.3) *36.3	(55.9) **39.1
Maximum	686.7	(93.8) *75.1	(58.7) *47.0	(73.7) **51.6
Minimum	308.2	(46.9) *37.6	(33.5) *26.8	(33.5) *26.8

Table 4: Biometric data (micrometers) for *Conochitina viiuae* sp. nov. Means are based on 15 partly flattened specimens from the Qusaiba-1 core hole, core 26, at 245.8 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: This new species is a typical *Conochitina* according the emended definition of this genus given by Paris et al. (1999). The specimen recorded at 251.1 ft (Plate I, 2) is totally compressed and thus its original diameter was ca. 41 μm (i.e. within the Dp range of the species; see Table 4). The folded and tilted base obscures its mucron.

Other very elongate *Conochitina* species ($L/Dp > 6$) have already been reported in the Ordovician and in the Silurian. Comparisons, however, are restricted here to Late Ordovician and to Silurian species. *Conochitina incerta* Eisenack, 1962 from the Late Ordovician of Baltoscandia has a sharper margin and a smaller mucron. *Conochitina rotundata* sp. nov. Paris et al. (this volume) from the late Katian of the Qusaiba-1 core hole has a sub-cylindrical vesicle and a base with a different shape (see discussion in Paris et al., this volume).

Conochitina proboscifera Eisenack, 1937 and even the “forma *truncata*” described by Laufeld (1974) have much thicker walls and a less slender silhouette. In the Llandovery of well D1-31 in Cyrenaica (eastern Libya) Paris *in* Molyneux and Paris (1985) identified as *C. proboscifera* a chitinozoan with a silhouette and a mucron very close to those of *C. viiuae* sp. nov. In spite there are no statistical data available for the total length of the Libyan form, it is included in the synonymy of *C. viiuae*, sp. nov. *Conochitina alargada* Cramer, 1967 has a stouter vesicle and no protruding mucron. *Conochitina leptostoma* Laufeld, 1974 from the early Wenlock of Gotland has also a slim vesicle, but its mucron is smaller and its flanks taper up to the aperture. *Conochitina praeproboscifera* Nestor, 1994 is wider (L/Dp ca. 4-4.5) and has a mucron less well-developed than *C. viiuae* sp. nov ($L/Dp > 6$). *Conochitina rara* Nestor, 1994 from the Aeronian of Estonia has an anti-apertural end, similar to that of *C. viiuae* sp.

nov., but the vesicle is much shorter.

Range and geographic distribution: In the Qusaiba-1 core hole, *Conochitina viiuae* sp. nov. has been recorded in core 26 (245.8 ft) where it represents 15% of the identified chitinozoans. A few less typical individuals are reported at 251.1 ft (Plate I, 2) and at 238.2 ft in the same well (Fig. 6; Table 19). These strata belong to the upper part of the *qusaibaensis* Biozone, which is assigned to the mid-Aeronian, based on the independent age control provided by graptolites of the *convolutus* Biozone (Zalasiewicz et al., 2007). This new species is likely rare and has a short range as it has not been reported yet in other subsurface chitinozoan assemblages from the Qusaiba Member. In all likelihood, the species is present (see synonymy) in a core sample from well D1-31 in Cyrenaica, eastern Libya (Molyneux and Paris, 1985; Paris, 1988a).

Subfamily **Spinachitininae** Paris, 1981

Genus *Spinachitina* Schallreuter, 1963 emend Paris et al., 1999

Type species: *Conochitina cervicornis* Eisenack, 1931

Spinachitina geerti sp. nov. Paris (Plate VII, 1, 4–5, 7–8)

? 1988 - *Conochitina* spp.; McClure, pl. VI, figs. 1-2 (non fig. 3).

1990 - *Spinachitina spinosa nomen nudum*; Van Grootel, pl. 8, figs. 11-15.

? 1991 - *Spinachitina bulmani* Jansonius, 1964; Al-Hajri, pl. 25 figs; 1-4 (non figs. 5-6).

v. 1991 - *Spinachitina maennili* (Nestor, 1980b); Paris, pl. 2 fig. 6a-b.

v. 1991 - *Spinachitina* sp. aff. *maennili* (Nestor, 1980b); Paris, pl. 2 fig. 7a-b.

v. 1995 - *Spinachitina maennili* (Nestor, 1980b); Paris et al., fig. 2 p. 79.

Derivation of the name: This species is dedicated to Dr Geert Van Grootel who described this species in his doctoral thesis under the name *Spinachitina spinosa* sp. nov. Unfortunately this species remained unpublished and has to be considered as a *nomen nudum* (see discussion below).

Holotype: Plate VII, 7, core 28, 240.7 ft, IGR 72371 (P42/4).

Type locality: Baq'a-4 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 28, sample from 240.7 ft, Aeronian

Paratypes: Plate VII, 1, core 28, 240.7 ft, IGR 72371 (Q42/1); Plate VII, 4, core 28, 240.7 ft, IGR 72371 (Q41/2); Plate VII, 8, core 28, 240.7 ft, IGR 72371 (Q41).

Material: 25 sorted specimens (ca. 200 additional individuals in the remaining unpicked organic residue).

Diagnosis: Large *Spinachitina* species with a conical chamber prolonged by a neck flaring near its fringed aperture; crown of well developed spines on the margin; randomly distributed robust spines on the chamber and on the neck; this ornamentation decreases on the chamber bottom and on the neck.

Description: The total length of this quite long chitinozoan (mean length: 252 μm ; length of the holotype: 231 μm) shows important variations (see Table 5; Figs. 11a–b) with L ranging from 322 μm (Plate VII, 4) to 141 μm (Plate VII, 5; the latter, however is possibly broken or teratological). The general silhouette of the vesicle is rather variable, with a fairly constant chamber width but a highly variable length due principally to the development of the neck. There is a positive correlation between the vesicle length (L) and the chamber length (lp) (Fig.

11b). Some elongate specimens have a long tubular neck ending with a flaring collarete. The aperture is serrated (Plate VII, 7a). The flanks taper progressively up to the base of the neck, which is separated from the chamber by a poorly differentiated shoulder and by a weak flexure (Plate VII, 1, 4). A slight constriction occurs in the third lower part of the chamber. A sharp margin corresponding to the maximum diameter of the chamber separates a slightly convex bottom from the flanks. The convexity of the anti-apertural end is accentuated by the folding downwards of the chamber bottom during compression (e.g. Plate VII, 7b). This fold usually obscures the apex of the vesicle and thus the antiapertural structure is not well-documented. A large flat circular area surrounded by a low rim is present (Plate VII, 1). The main discriminating characters of this species are the combination of the crown of fairly long spines running along the margin, and the robust and well-developed spines on the chamber (Plate VII, 1, 7b, 8). The spiny crown is composed of ca. 30 quite long tapering spines (length up to 12 μm), densely and regularly distributed along the margin (Plate VII, 7b, 8) and directed anti-aperturalwards. Robust but shorter conical spines are randomly distributed on the chamber (Plate VII, 7b, 8). This spiny ornamentation fades away toward the neck where they are reduced to granules or to blunt cones. The chamber bottom below the crown surrounding the margin is smooth (Plate VII, 1) or carries small granules (Plate VII, 7b, 8).

Measurements (Table 5; Figs. 11a–b).

	L	lp	Dp	dc	dcoll.	l. spines
Holotype	231	171	(68.7) *55.0	(55.3) **38.7	(57.0) **40.0	6.7
Mean	252	168	(82.4) *65.9	(54.6) **38.2	(58.3) **40.8	5.7
Maximum	322	208	(101) *81	(65.3) **45.7	(65.3) **45.7	10.1

Minimum	141	121	(53.6)	(43.6)	(43.6)	3.5
			*42.9	**30.6	**30.6	

Table 5: Biometric data (micrometers) for *Spinachitina geerti* sp. nov. Means are based on 15 compressed specimens from the Baq'a-4 core hole, core 28 at 240.7 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: Van Grootel (1990, p. 78-80) described a chitinozoan he named *Spinachitina spinosa* sp. nov. from the subsurface of the Brabant Massif (Belgium). Unfortunately this new species has not been published. According to the Zoological Code of Nomenclature it must be regarded as a *nomen nudum*. In his dissertation, Van Grootel gave an excellent description and provided a complete set of measurements of his new species. However, no SEM illustrations were provided and the reflected light microscope images (Van Grootel, 199; pl. 8, figs. 11-15) do not fully show the ornamentation. Consequently, for the stability of nomenclature it is preferred to designate another holotype from the present Saudi Arabian material and to leave “*Spinachitina spinosa*” as a *nomen nudum*. The specimens recorded by Van Grootel (1990) show the same important variations of the vesicle length (L) ranging from 140 to 333 μm (mean: 226 μm) for the Belgian population (see Table 5, for comparison). Because the occurrence of a spiny ornamentation on its flanks, *Spinachitina geerti* sp. nov. clearly differentiates from the other early Silurian *Spinachitina* species, especially from *S. fragilis* (Nestor, 1980a), which has a similar silhouette (e.g., see Bourahrouh, 2002; Butcher, 2009). *S. maennili* (Nestor, 1980b) has a sub-cylindrical vesicle and no ornamentation on the chamber. A few Late Ordovician species have spiny walls such as *S. cervicornis* (Eisenack, 1931) and *S. taugourdeau* (Eisenack, 1968). These two species, however, have more strongly developed processes on their margin. *S. imperita* (Dicevitchius, 1971) has a different silhouette as its cylindrical neck is longer than the chamber. Moreover, its wall seems

glabrous.

During previous investigation on the subsurface chitinozoans from Saudi Arabia, rare *Spinachitina* specimens with a spiny ornamentation on the chamber have been recorded in cores 18 to 20 of the UDYN-1 well. Some of the recovered specimens with subcylindrical vesicles were tentatively referred to *S. sp. aff. maennili* by Paris (1991). Other ones with less obvious spines on the chamber were assigned to *S. maennili* (Nestor, 1980b). Owing to the variations recorded in the present population of *S. geerti* sp. nov., the UDYN-1 specimens are included in the synonymy list of the new species. Other *Spinachitina* specimens recorded in well “QA” (Al-Hajri, 1991, pl. 25, figs. 1-4; see synonymy above) could also belong to *S. geerti* sp. nov. because the tiny granules occurring on their transparent neck may represent spine remains.

Range and geographic distribution: In the Baq’a-4 core hole, *S. geerti* sp. nov. has been recorded exclusively in cores 28 (240.7 ft) where it is abundant, and in core 19 (163.0 ft) (very rare; see Fig. 7). The corresponding strata belong to the upper part of the *hemeri* Biozone, which is assigned to the Aeronian, most likely to the mid-late Aeronian (see discussion above). Van Grootel (1990) recorded his “*Spinachitina spinosa*” nomen nudum in samples from the subsurface of the Brabant Massif (Belgium) in the Kortrijk 83W-421 (208.3 and 232.1 m), Kortrijk 83W-44 (168.0 to 215.5 m) and Steenkerke 50E-134 (267.0 and 323.0 m) core holes. According to Van Grootel (1990, p. 80) the corresponding strata range from the Aeronian to the Telychian (middle part of the *sedgwickii* to the *crispus* graptolite zones). In Saudi Arabia, if one accepts the synonymy proposed here, *S. geerti* sp. nov. ranges through the Aeronian as documented in the UDYN-1 and Baq’a-4 wells. However, its relative abundance is very low in the early Aeronian. A specimen recorded in core 19 (160.3 ft) in the Baq’a-4 well displays a crown of numerous (ca. 50) short blunt spines on the margin and bears tubercles on its flanks (Plate VIII, 2). It is provisionally referred to *S. geerti* sp. nov. as

it may correspond to a corroded specimen. If the suggested synonymy of the specimens recorded by Al-Hajri (1991) in the “QA” well is confirmed by SEM observations, the species is also present in the Qusaiba Member in the subsurface of the Tabuk area (northern Saudi Arabia).

Family **Lagenochitinidae** Eisenack, 1931, emend Paris, 1981

Subfamily **Cyathochitinae** Paris, 1981

Genus ***Cyathochitina*** Eisenack, 1955b, emend Paris et al., 1999

Type species: Conochitina campanulaeformis Eisenack, 1931

Cyathochitina neolatipatagium sp. nov. Paris (Plate VI, 7–8, 11)

1988 - *Cyathochitina campanulaeformis* (Eisenack, 1931); McClure, pl. VII, fig. 16.

1991 - *Cyathochitina latipatagium* Jenkins, 1970; Al-Hajri, pl. 28, fig. 8; pl. 29, fig. 1.

1991 - *Cyathochitina kuckersiana* (Eisenack, 1934); Al-Hajri, pl. 37, figs. 3 and 6.

1994 - *Cyathochitina kuckersiana* (Eisenack, 1934); Nestor, pl. XXIII, figs. 7-8

v. 2003 - *Cyathochitina neolatipatagium nomen nudum*; Paris, pl. 6, figs. 7-8, 11.

Derivation of the name: the name indicates that this new species is similar to *C. latipatagium*, which is a Late Ordovician species.

Holotype: Plate VI, 8, core 14, 136.5 ft, IGR 72293, (Q40/4).

Type locality: Qusaiba-1 core hole, core 14, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation, core 14, 135.5 ft, mid-Aeronian (*hemeri* Biozone).

Paratypes: Plate VI, 7, core 14, at 133.45 ft, IGR 72298, (Q50); Plate VI, 11, core 14, at 136.5 ft, IGR 72293, (Q40).

Material: 1585 specimens picked from the organic residues of core 14 (4 samples, see Fig. 6) from the Qusaiba-1 core hole. Some of the sorted specimens were used for $\delta^{13}\text{C}_{\text{chit}}$ analyses and for chemical organic analyses of the chitinozoan wall (Jacob et al., 2007); 114 specimens picked in cores 25 and 22 from the Baq'a-3 core hole (Fig. 8; Table 21).

Diagnosis: Large *Cyathochitina* species with a short cylindrical neck, a thickset conical chamber, and a very wide and rather thick carina extending perpendicularly from a thick-walled margin; the glabrous chamber has a corrugate surface; concentric rim pattern occurs on the carina.

Description: This *Cyathochitina* species is quite large with the diameter of the chamber (excluding the carina) ranging from 117 to ca. 240 μm (mean diameter: 168 μm) (see Table 6; Fig. 12). The holotype is partially compressed along its longitudinal axis. Consequently, the actual lengths of the vesicle and neck are likely higher than the measures reported on Table 6. This vertical compression is due to its wide diameter (maximum diameter of the vesicle, including the carina = 227 μm) exceeding the vesicle length and to the thickened margin that prevent the lateral flattening (the vesicle settles on its bottom, instead of on its flanks as is the rule for elongated vesicles). Such oriented deformation is frequently observed in the examined populations (Plate VI, 7–8). The neck is cylindrical and its length does not exceed the length of the thickset chamber. The flanks are normally straight (no shoulder) and taper rapidly toward the conspicuous flexure. The widened lower part of the chamber of the paratype (Plate VI, 7) is due to the differential compression of the flanks and of the occurrence of a thickened

margin. The vesicle surface is glabrous, but variably developed corrugations are visible on the chamber wall. This pattern results from cross distribution of low longitudinal and horizontal elevations (or of discrete thickenings of the wall). The carina is well-developed (mean width: 22.7 μm ; see Table 6) and displays concentric thickened rims or ridges (visible mainly in transmitted light microscope). This double-walled carina, with a rounded border (Plate VI, 7) is oriented perpendicular to the margin. Its width is variable (ranging from 10 to 44 μm) and seems generally correlated with the chamber diameter (Fig. 12). The lateral compression of the vesicle (flattening perpendicularly to the vesicle axis) generates radial folds of this carina (see left side of the carina on Plate VI, 7).

Measurements (Table 6; Fig. 12).

	L	lc	Dp	Dc	l. carina
Holotype	175	87	160.1	50	31
Mean	199.6	94.3	167.6	61.8	22.7

Minimum	134	40.2	117.3	39.6	10.1

Table 6: Biometric data (micrometers) for *Cyathochitina neolatipatagium* sp. nov. Means are based on 40 specimens from the Qusaiba-1 core hole, core 14 at 136.5 and 133.35 ft depth (no correction factor for compression used as most vesicles are three-dimensional; see Pl. 6).

Discussion: *C. neolatipatagium* sp. nov. is distinguished from most the other *Cyathochitina* species, except from *C. latipatagium* Jenkins, 1969, which also has a very wide carina. The carina of the latter, however, is thinner than the carina of *C. neolatipatagium*, which chamber has a thickened margin. The widest part of this chamber is located just above the carina. The two species are very similar, but it is unlikely that *C. latipatagium* specimens can have a

“Lazarus” distribution with more than 5 million years between their ranges. For that reason and based on the slight differences listed above this new species is proposed. McClure (1988, pl. VII, fig. 16) and Al-Hajri (1991) illustrated *Cyathochitina* specimens with a large carina from the Qusaiba Member of the Qalibah Formation from the subsurface of the Tabuk and Qasim areas that most likely belong also to *C. neolatipatagium* sp. nov. (see synonymy list). Nestor (1994) illustrated individuals identified as *Cyathochitia kuckersiana* (Eisenack 1934) from the Varkla core in Estonia. One of the specimens recorded by this author (pl. XXIII, fig. 8) in strata from the Raikülla regional stage (Aeronian) shows the circular rims and the rounded edge of *C. neolatipatagium* sp. nov. In our opinion, this justifies the synonymy proposed here, even if Nestor (1994, p. 80) considers the Late Ordovician and the early Silurian *Cyathochitina* with a morphology recalling *C. kuckersiana* as probable intraspecific variations of this species.

Range and geographic distribution: The new species is extremely abundant (up to 70% of the recorded specimens; see Fig. 6; Table 19) in the upper part (cores 14 to 16) of the Qusaiba-1 core hole. The corresponding strata represent part of the Qusaiba Member of the Qalibah Formation, assigned to the mid-Aeronian based on an independent graptolite control (Zalasiewicz et al., 2007). *C. neolatipatagium* sp. nov. occurs also in the Baq’a-3 core hole where it is the dominant species in core 22 at 206.9 ft (39% of the identified chitinozoans; Fig. 8). In core 25, at 229.7 ft, it represents only 1%, but in a much more abundant assemblage. In the Baq’a-3 well the corresponding samples are still from the Qusaiba Member, but they are referred to the upper part of the *obtusa* Biozone, which is tentatively assigned to the mid-Telychian (see discussion above, and Fig. 9). The distribution of *C. neolatipatagium* sp. nov. in the Qusaiba Member is striking. It seems to be controlled by sporadic “blooms”, by environmental changes (e.g., more silty facies; see Table 1 and 3) or by variations in their predation. *C. neolatipatagium* sp. nov. is only reported from Saudi Arabia.

If one accepts the proposed synonymy, this new species occurs also in the Qusaiba Member of the Qalibah Formation of the Qasim and Tabuk areas in Saudi Arabia, and in the Aeronian of Estonia (Varkla core; see Nestor, 1994).

Subfamily **Ancyrochitininae** Paris, 1981

Genus ***Ancyrochitina*** Eisenack, 1955a

Type species: Conochitina ancyrea Eisenack, 1931

Ancyrochitina alhajrii sp. nov. Paris (Plate X, 2, 4; Plate XI, 6)

v. 2005- *Ancyrochitina alhajrii nomen nudum*; Paris, pl. 4, figs. 2a-b, 4a-b.

Derivation of the name: this new species is dedicated to Sa'id Al-Hajri (Saudi Aramco) for our fruitful and long-term scientific collaboration.

Holotype: Plate X, 4; core 47, at 431.7 ft, IGR 72339 (O40).

Type locality: Baq'a-3 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 47, sample from 431.7 ft, early Telychian

Paratype: Plate X, 2; core 47, at 431.7 ft, IGR 72339 (O45).

Material: 239 specimens picked in the organic residues from cores 47 to 42 (Fig. 8) of the Baq'a-3 core hole.

Diagnosis: *Ancyrochitina* species with a well-developed cylindrical neck, a flaring collarette

and a thickset conical chamber with a flat to slightly convex bottom; four to six long hollow processes pointing down from the margin; densely distributed minute hairs-like spines on the flanks and base of the neck.

Description: This medium-sized new *Ancyrochitina* species (mean vesicle length ca. 127 μm ; see Table 7; Figs. 13a–b) shares all the characteristics of the genus as defined by Eisenack (1955a). The well-developed cylindrical neck terminates in a slightly flaring membranous collarete. A straight lip surrounds the aperture (Plate X, 4a). The length of the neck and collarete exceeds that of the chamber (mean: $l_c/l_p > 1$). A conspicuous flexure separates the neck from the chamber. No shoulder is observed on this thickset conical chamber, which diameter is larger than its length (i.e., $D_p/l_p > 1$). The bottom of the chamber is flat or slightly convex. This convexity is frequently accentuated during the compression of the vesicle, which causes the folding of the bottom wall inside of the chamber (Plate X, 4a). The margin is fairly sharp and bears four to six long and wide hollow processes (process length up to ca. 84 μm ; diameter ca. 10 μm). These processes taper progressively toward their rounded distal end and are oriented more or less parallel to the longitudinal axis of the vesicle. The most discriminating character is the occurrence of randomly distributed thin hairs all over the vesicle. These slender hairs (diameter less than 0.5 μm ; length ranging from 5 to 10 μm ; see Plate X, 2b, 4b) are smaller towards the aperture. The granules stuck on the wall of some specimens (Plate X, 4b) are “exotic” (not part of the ornamentation of the vesicle).

Measurements (Table 7; Figs. 13a–b).

	L	Lc	Dp	Dc	Dcoll.	l. processes
Holotype	117.3	63.7	(82.1) *65.7	(30.2) **21.2	(40.2) **28.2	46.9
Mean	126.7	63.1	(79.5) *63.6	(33.1) **23.2	(42.3) **29.6	50.8

Maximum	160.8	93.8	(93.8) *75.1	(41.9) **29.4	(50.3) **35.2	83.8

Table 7: Biometric data (micrometers) for *Ancyrochitina alhajrii* sp. nov. Means are based on 37 compressed specimens from the Ba'qa-3 core hole, core 47 at 431.7 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: Many *Ancyrochitina* species have a silhouette, or processes similar to those of *A. alhajrii* sp. nov. The latter, however, is easily distinguished by its distinct hair-like vesicle ornamentation. The specimen (Plate XI, 6), from the Baq'a-3 well (core 47 at 431.7 ft) does not clearly show the hair-like ornamentation of the chamber because organic matter coats the wall. The apparent branching of one process of this specimen is interpreted as an artifact (organic fragment stuck on the process). In some cases the hollow processes of *A. alhajrii* show a more or less cellular pattern like the processes of *Plectochitina pseudoagglutinans*. The latter, however, lacks the hairy ornamentation on its chamber.

Range and geographic distribution: *A. alhajrii* sp. nov. is only recorded in the Baq'a-3 core hole, in cores 47 to 42 (431.7 to 388 ft; Fig. 8; Table 21). It is the dominant species in three samples (e.g. 42% at 408.7 ft; see Fig. 8; Table 21) belonging to the Qusaiba Member of the Qalibah Formation. The corresponding interval corresponds to the lower part of the *macclurei* Biozone (*merrelli* and *crassicarinata* subbiozones *pro-parte*) and is assigned to the early Telychian (Figs. 8–9), based on graptolite evidence (*turriculatus* Biozone).

Ancyrochitina camilleae sp. nov. Paris (Plate VIII, 1, 6)

v. 2005- *Angochitina camilleae nomen nudum*; Paris, pl. 2, figs. 1 and 6.

Derivation of the name: this species is dedicated to my granddaughter Camille Paris

Holotype: Plate VIII, 1, core 19, at 163.0 ft, IGR 72364 (P41/4).

Type locality: Baq'a-4 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 19, sample from 163.0 ft, Aeronian.

Paratype: Plate VIII, 6, core 19, at 163.0 ft, IGR 72364 (P44).

Material: 35 specimens have been picked from the organic residues of cores 19 to 23 (Fig. 7; Table 20) from the Baq'a-4 core hole (about 350 specimens in the organic residue, as only 10% was picked; Table 2).

Diagnosis: *Ancyrochitina* species with a thickset conical chamber; fairly short neck terminated by a flaring collarette with serrate lips; smooth vesicle walls; six very long tapering processes briefly branched distally.

Description: This small sized species (mean vesicle length ca. 110 μm ; Table 8; Figs. 14a–b) displays all the generic characters listed by Eisenack (1955a) for *Ancyrochitina*. The conical chamber has straight (Plate VIII, 1) or slightly convex flanks (no shoulder) tapering toward a conspicuous flexure (the convexity of the flanks may be accentuated during the compression of the vesicle). The diameter and the length of the chamber are in the same range of values, ca. 80 to 90 μm . The short cylindrical part of the neck is prolonged with a well-developed collarette (collarette length close to the half of the length of the neck). The prosome is usually implanted in the base of the neck, which is therefore not fully compressed (correction factor of 0.9). Short spines (Plate VIII, 1) or minute serrations (Plate VIII, 6) border the lips surrounding the aperture. The vesicle wall is usually smooth; the granules on the holotype

(Plate VIII, 1) result from amorphous organic matter adhering to the wall. The structure of the six long processes originating on the margin, sub-perpendicular to the vesicle axis, constitutes the most distinct character of this new species. These extremely long hollow processes (mean total length of the processes, including their branches = 55 μm , but reaching 87 μm for some specimens) taper very gently distally from a short conical base. The first branching occurs at about the last fourth of the total length. The resulting short branches are thinner and may subdivide up to four times. These successive short branches simulate a sort of distal fleuron; Plate VIII, 1, 6).

Measurements (Table 8; Figs. 14a–b).

Table 8: Biometric data (micrometers) for *Ancyrochitina camilleae* sp. nov. Means are based on 30 compressed specimens from the Ba'qa-4 core hole, core 19 at 163.0 ft depth (raw data: between brackets; * correction factor: 0.8; **correction factor: 0.7; ***correction factor: 0.9.

Discussion: This new species is reminiscent of several other Late Ordovician or early Silurian *Ancyrochitina* with very long processes and without spines on the neck or on the chamber. Among the closest species, *A. ramosaspina* Nestor, 1994 is larger and the branching of its

processes occurs at about one half of their total length; each resulting branch is more robust. Fairly similar chitinozoans (but with a different branching pattern) tentatively identified as *A. cf. ramosaspina* occur in the lower Llandovery of the Murzuk Basin, Libya (Paris et al., 2012, pl. 4, figs. 2, 5-6). *A. porrectaspina* Nestor, 1994 has shorter processes with a different branching pattern (less numerous). *A. longispina* Achab, 1978 has a quite close silhouette. However, its neck is better developed and the pattern of the branching of its long processes is also different (first branches perpendicular to the main trunk and occurring more proximally than in *A. camilleae* sp. nov.). Quite similar specimens previously identified as *A. cf. longispina* have been recorded in the basal Silurian of the Kufra Basin, Libya (Paris, unpublished).

Range and geographic distribution: *A. camilleae* sp. nov. is only recorded in the Baq'a-4 well, in cores 19 to 23 from the Qusaiba Member of the Qalibah Formation. The corresponding strata are assigned to the Aeronian, and most likely to the late Aeronian as early Telychian graptolites of the *guerichi* Biozone occur quite close above these strata (Zalasiewicz et al., 2007). *A. camilleae* is the index species of the chitinozoan subbiozone defined herein, in the upper part of the *hemeri* Biozone (Fig. 9).

Genus *Plectochitina* Cramer, 1964

Type species: *Plectochitina carminae* Cramer, 1964.

Plectochitina alisawyahensis sp. nov. Paris (Plate IX, 4, 6–7; Plate XI, 4; Plate XII, 7; Plate XV, 4–6, 8–9)

1988 - *Clathrochitina sylvanica* Jenkins, 1970; McClure, pl. XI, figs. 4-6, 8-9 (non fig. 10)

1988 - *Plectochitina carminae* Cramer, 1964; McClure, pl. XI, fig. 12.

? 1991 - *Plectochitina pseudoagglutinans* Taugourdeau, 1963; Al-Hajri, pl. 34, fig. 6 (non figs. 2-5).

v. 1993 - *Plectochitina combazii* Cramer, 1967; Paris, pl. 1, figs. 7-8.

v. 2005 - *Plectochitina alisawyahensis nomen nudum*; Paris, pl. 3, figs. 4,6; pl. 5, fig. 4; pl. 6, fig. 7; pl. 9, figs. 4-5, 8.

Derivation of the name: The species name refers to the locality Al Isawyah, in Saudi Arabia.

The ISWH EW-9 well drilled in this locality yielded the first specimens of the new species described here.

Holotype: Plate XII, 7, core 40, sample from 370.4 ft, IGR 72332 (P44/3).

Type locality: Baq'a-3 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 40, sample from 370.4 ft, early Telychian.

Paratypes: Plate XV, 4, core 30, sample from 271.8 ft. IGR 72319 (Q45/3); Plate XV, 5, core 30, sample from 271.8 ft. IGR 72319 (R45); Plate XV, 8, core 30, sample from 271.8 ft, IGR 72319 (R45/1); Plate XV, 9, core 27, sample from 250.5 ft, IGR 72316 (R41/1).

Material: 304 specimens have been picked from the organic residues from Baq'a-3, cores 16 to 56 (Fig. 8; Table 21) and 112 specimens from the organic residues from Baq'a-4, cores 7 to 17 (Fig. 7; Table 20). Several hundred additional specimens were available in the unpicked organic residues (see Tables 2–3) and in the ISWH EW-9 material (see below).

Diagnosis: *Plectochitina* species with flat-based conical chamber and short cylindrical neck flaring around the aperture; fairly sharp margin carrying a crown of long and wide cell-like processes; these simple or anastomosed processes are connected at their distal end, either as

several separated sets, or all together.

Description: This spectacular and rather polymorphic species (Table 9; Figs. 15a–b; Plate XV, 4–6, 8–9) shows all the generic characters of *Plectochitina* as defined by Cramer (1964), i.e. a differentiated chamber/neck and cell-like processes. The vesicle is relatively small (average vesicle length: ca. 110 μm) with regard to the processes (lproc.: up to 130 μm length) (see Table 9 and Fig. 15b). The conical chamber has a flat base and a sharp margin. The straight flank (no shoulder) passes to a short flaring neck through a weakly individualized flexure. This neck, including the collarete, represents close to the half of the vesicle length (processes not included) (Plate XV, 4–5, 9). A membranous flared lip surrounds the straight aperture. The vesicle walls are usually entirely smooth. A specimen with a few random spines on the flexure has been observed (Plate IX, 7). The discriminating character is the very large crown of cell-like (vesicular) processes that runs around the margin. These numerous processes (about 15) are frequently much longer than the chamber. The diameter of these processes is quite variable, ranging from very wide, cylindrical or gently tapering isolated processes (e.g. Plate XV, 5) to slender elements anastomosing distally (Plate XV, 8). The end of the processes are connected, either by a hollow rim (Plate XV, 5) or more frequently arranged into three or four “buckle-like” structures around the margin (Plate XV, 4, 8–9). The processes originate directly from the margin wall, or from a membranous carina –like expansion (Plate XV, 6)

Measurements (Table 9; Figs. 15a–b).

	L	lc	Dp	lc	lcoll.	lproc.
Holotype	127.3	60.3	(77.1) *61.70	(33.5) **23.5	(35.2) **24.6	83.8
Mean	109,6	49,6	(78,1) *62.5	(32.5) **22.8	(36.0) ** 25.2	67.4

Maximum	140.7	83.8	(100.5) *80.4	(50.2) **35.2	(43.6) **30.5	130.7
Minimum	83.8	30.2	(63.7) *51	(23.5) **16.5	(23.5) **16.5	33.5

Table 9: Biometric data (micrometers) for *Plectochitina alisawyahensis* sp. nov. Means are based on 30 compressed specimens from the Ba'qa-3 core hole, core 40 at 370.4 ft depth, and core 49 at 450.1 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: The specimens identified as *Clathrochitina sylvanica* by McClure (1988; pl. XI, figs. 4-6, 8-9,11) from the subsurface of Tabuk and Qasim areas show the same variable pattern of arrangement of their cell-like processes as *P. alisawyahensis* sp. nov., from the Baq'a-4 and Baq'a-3 core holes. With the exception of the specimen (pl. XI, fig. 10), which is referred to *P. clathrospinosa*, all McClure's (1988) specimens are therefore included in the synonymy list of *P. alisawyahensis* sp. nov.

Several other *Plectochitina* species have been described in the Silurian of northern Gondwana regions. *P. saharica* (Taugourdeau, 1962) from the early Silurian of SE Algerian Sahara is probably the most similar species. Its processes appear less well-developed and the available illustration does not allow a detailed comparison. *P. fenesdiculae* Al-Ameri, 1989, and *P. lubnia* (Al-Ameri, 1989), from the subsurface of Tripolitania (Libya) have longer necks and a different arrangement of their processes. *P. combazii* Cramer, 1967 described in the Llandoverly of Spain has numerous very thin processes. The provided illustration, however, does not demonstrate the presence of an external rim joining the distal end of the processes. *P. irregularis* Cramer and Diez, 1978 described from the Lochkovian of Spain has very thin anastomosing processes and a better-developed neck. *P. carminae* is quite close to *P.*

alisawyahensis sp. nov., but it displays a different arrangement of its cell-like processes (fewer and thinner proximal branches; higher number of anastomosing knots). *P.*

sansalvadorensis (Schweineberg, 1987) from the Gorstian of Spain has processes with a similar anastomosing pattern, but its neck is much more developed than that in *P.*

alisawyahensis sp. nov.

Some Late Ordovician species have morphologies similar to *P. alisawyahensis* sp. nov. The processes of *P. concinna* (Achab, 1978) from the Late Ordovician of eastern Canada has quite a similar anastomosing pattern but the resulting “buckle-like” sets of processes are much shorter than those of *P. alisawyahensis* sp. nov. *P. sylvanica* (Jenkins, 1970) from the late Katian of Oklahoma has thinner processes with a different anastomosing pattern.

Range and geographic distribution: *P. alisawyahensis* sp. nov. is extremely well-represented in the upper part of the Qusaiba Member of the Qalibah Formation in Saudi Arabia. It is quite abundant in the upper part of the Baq'a-4 well (Fig. 7; Table 20), where it occurs with *A. macclurei*, and with graptolites of the *guerichi* Biozone (Fig. 9). *P. alisawyahensis* sp. nov. occurs irregularly along the investigated ca. 367.9 ft (113.2 m) thick sequence in the Baq'a-3 well (from core 56 to core 16 inclusive). It is a rather long ranging species, which is recorded in the *macclurei* through *silurica* chitinozoan biozones (Fig. 8; Table 21) of Telychian age (Figs. 8–9). This new species has been reported under various names (see synonymy list) in other wells in Saudi Arabia (McClure, 1988; Al-Hajri, 1991). The most productive samples were from ISWH EW-9 well, where the species is the dominant chitinozoan species in cutting samples from 3478 ft (1058 m) to 3603 ft (1096 m), and in a core sample from 3694.7 ft (1093.5 m). It is less abundant in the other investigated core samples at 1095.5 m to 1098 m (Paris, 1993). This species and the associated chitinozoans allow now to firmly assign this part of the ISWH EW-9 well to the Telychian.

Plectochitina alnaimi sp. nov. Paris (Plate III, 6; Plate IV, 9; Plate V, 2, 10)

1991 – *Plectochitina* sp. 1; Al-Hajri, pl. 30, fig. 5.

2005 – *Ancyrochitina* nov. sp. A; Paris, pl. 3, fig. 9; pl. 2, figs. 3 and 10.

Derivation of the name: This new species is dedicated to Abdulla Al-Naim, the Vice President for Exploration in Saudi Aramco who has been an active supporter of the CIMP/Saudi Aramco project from its inception.

Holotype: Plate V, 2, core 14, sample from 140.10 ft; IGR 72291 (Q42).

Type locality: Qusaiba-1 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 14, sample from 140.1 ft, Aeronian.

Paratype: Plate V, 10, core 16, sample from 150.8 ft, IGR 72286 (R44).

Material: 2178 specimens picked from cores 27 to 32 (136.5 to 217.2 ft depth) from the Qusaiba-1 core hole (Fig. 6) and several thousand additional specimens in the corresponding unpicked residue (Table 1).

Diagnosis: Small *Plectochitina* species with a conical chamber and a short cylindrical neck (L/lc close to 2) ended by a flaring collarete; granules or blunt cones cover the vesicle wall; up to eight bi- or more rarely multi-rooted processes with a spongy to cell-like (vesicular) internal structure.

Description: This chitinozoan is quite small: its vesicle length (L) ranges from ca. 74 to 134 μm , with an average length of ca. 110 μm . The holotype ($L=103.9 \mu\text{m}$) is shorter because the lips are partly folded within the aperture (Plate V, 2). The straight flanks (no shoulder observed) taper rapidly toward a conspicuous flexure. This gives a thickset aspect to the

chamber, where the width is usually greater than its length (mean D_p/l_p close to 1.35), even after correction for compression (see Table 10). Randomly distributed granules or fairly large blunt cones occur on the vesicle wall, including the chamber bottom (Plate V, 10). These granules fade away on the neck. Minute interrupted ridges present between the granules make a sort of irregular array with a more or less horizontal pattern (only visible by SEM). The sub-cylindrical neck ends with a membranous collarete flaring toward the aperture (straight to finely serrate lips). The chamber bottom is flat to slightly convex but depending on the compression pattern, its wall may be folded within the chamber (Plate V, 10) or it can be totally tilted (Plate V, 2). Six to eight processes of variable length and with a “spongy” to cell-like (vesicular) internal structure (visible in transmitted light) are located on the margin. They are bi-rooted (Plate V, 2), occasionally multi-rooted and rarely simple with a widened base. These processes are very brittle and only the proximal part may be preserved. For that reason the average length (ca. 20 μm) of the processes given on Table 10 is largely under-estimated. When fully preserved the tapering distal part of the processes represents at least two third of their total length (Plate V, 2).

Measurements (Table 10; Figs. 16a–b).

Table 10: Biometric data (micrometers) for *Plectochitina alnaimi* sp. nov. Means are based on 55 compressed specimens from the Qusaiba-1 core hole, core 14 at 140.1 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: When collecting the biometric data with a transmitted light microscope at high magnification, the processes of this chitinozoan show constant spongy internal structure. Cramer (1964) and Paris et al. (1999) regarded this character as diagnostic for *Plectochitina*. The former generic assignment of this new species to *Ancyrochitina*, based exclusively on SEM, is therefore modified here (see synonymy). Al-Hajri (1991, pl. 30, fig. 5) illustrated a chitinozoan sp. nov. with a silhouette, multi-based processes and dimensions fitting with the present definition *P. alnaimi* sp. nov. (see synonymy).

Plectochitina alnaimi sp. nov. belongs to the *Plectochitina* forms with bi- or multi-rooted relatively short processes. Such taxa are quite common in the early Silurian and may be confused with *Ancyrochitina* species illustrated by SEM. *A. diabolus* Eisenack, 1937 from the Silurian of the Baltic area has a similar silhouette, but its robust processes are not described as bi-rooted or with a spongy internal structure. *A. magna* Nestor, 1982 from the Wenlock of Baltoscandia is much larger and has processes with a wider proximal part. *A. obesa* Tsegeljuk, 1982 from the early Wenlock of Podolia has a similar silhouette, but not bi-rooted processes. *A. spinosa* Al-Ameri, 1989 has a conspicuous shoulder and no bi-rooted processes. *A. alhajrii* sp. nov. is differentiated from *P. alnaimi* sp. nov. by the lack of processes with a spongy to cell-like structure, and because of its hair-like ornamentation covering the vesicle walls.

Range and geographic distribution: *Plectochitina alnaimi* sp. nov. is extremely abundant in most of the samples from the Qusaiba-1 core hole (Fig. 6; Table 19). It is the dominating species of the *hemeri* Biozone (70% of the chitinozoans recorded at 140.1 ft in the type

stratum). The species, which has apparently its LAD at 136.5 ft, is already present but less abundant in the upper part of the *qusaibaensis* Biozone penetrated by the Qusaiba-1 core hole (Fig. 6; Table 19). Surprisingly it is missing in the main part of the *alargada* Biozone (Fig. 6). In the Qusaiba-1 core hole, the coexistence of *P. alnaimi* sp. nov. with graptolites of the *convolutus* Biozone supports a mid-Aeronian age for the range of the species. If one accepts the proposed synonymy, the new species is also present in northern Saudi Arabia, in sample 10 from the “QA” well of the Tabuk area (Al-Hajri, 1991).

***Plectochitina jacquelineae* sp. nov.** Paris (Plate XIV, 4, 6)

1988 - *Ancyrochitina* sp.; McClure, pl. X, fig. 3.

1988 - *Ancyrochitina merga* Jenkins, 1970; McClure, pl. X, fig. 8.

? 1988 - *Ancyrochitina erichseni* Sommer and Van Boekel, 1963; McClure, pl. X, fig. 7.

? 1988 - *Clathrochitina clathrata* Eisenack, 1959, 1963; McClure, pl. XI, fig. 1 (non. fig. 2).

v. 1993 - *Plectochitina jiangsuensis* Geng et al., 1987; Paris, fig. 2.

Derivation of the name: The species is dedicated to my wife Jacqueline Paris for her patient support during my career.

Holotype: Plate XIV, 6, core 34, sample from 306.0 ft, IGR 72323 (P43).

Type locality: Baq'a-3 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 34, sample from 306.0 ft, early Telychian.

Paratype: Plate XIV, 4, core 34, sample from 306.0 ft, IGR 72323 (R43).

Material: 52 specimens were picked from the organic residue of core 34 of the Baq'a-3 core

hole (Fig. 8; Table 21). More than one hundred additional specimens are available in the remaining organic residue (see Table 3) and in the material from the ISWH EW-9 well (see below).

Diagnosis: *Plectochitina* species with granulose flanks; conical chamber with a well-developed cylindrical neck flaring around the aperture; rounded margin with a crown of ca. 20 to 30 very short processes; these spongy processes are simple or have short branches at their distal end.

Description: This medium sized chitinozoan (L ranging from ca. 74 to 174 μm ; mean length: 130 μm ; holotype length: 144 μm ; see Table 11) has a conical chamber with rapidly tapering flanks and a flat base. The vesicle wall is rugose to granular. No shoulder is present on the chamber but a conspicuous flexure separates the tapering straight flanks from a well-developed neck (mean value of the ratio l_c/L close to 0.61; see Fig. 17). Straight or very finely serrate lips surround the aperture of this cylindrical to gently flaring neck (Plate XIV, 4a, 6a). Occasionally, a membranous expansion of the prosome (with septa) extends out of the aperture (Plate XIV, 6a). This prosome is located deeply within the neck (proximal part originating near the flexure). The rounded margin carries a crown of numerous (usually 20 to 30) short spongy processes (length ranging from 3.5 to 13.4 μm ; mean = 7.3 μm). In a few cases, a very short membrane (less than 3 μm) joins the base of these processes, which may branch in a fleuron-like structure at their distal end (Plate XIV, 4b). In other cases the processes taper or have a blunt end (Plate XIV, 6b). In transmitted light microscope, the short processes display a spongy structure, which supports an assignment to *Plectochitina*, rather than to *Ancyrochitina* (see discussion below).

Measurements (Table 11; Figs. 17a–b).

	L	Lc	Dp	Dc	Dcoll.	lproc.

Holotype	144.1	86.6	(95.9) *76.7	(35.1) *28.1	(48.4) **33.9	10.1

Maximum	174.2	107.2	(108.9) *87.1	(43.6) **30.5	(53.6) **37.5	13.4
Minimum	73.7	46.9	(62.0) *49.6	(30.2) **21.2	(26.8) **18.8	3.5

Table 11: Biometric data (micrometers) for *Plectochitina jacquelineae* sp. nov. Means are based on 40 compressed specimens from the Baq'a-3 core hole, core 34 at 306.0 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: Because the occurrence of a membrane joining the base of the processes of some specimens this species could be assigned to *Anthochitina*. In the present material this character is very unusual and the most common feature is the existence of processes directly fixed to the margin, such as on the holotype (Plate XIV, 6b). A generic assignment to *Ancyrochitina* is also conceivable, but the spongy structure of the processes better supports the assignment to *Plectochitina*, even if the occurrence of very short and numerous processes is an uncommon feature for this genus. Al-Hajri (1991; pl. 30, fig. 4) illustrated a chitinozoan with a membranous expansion (ending with spines) around the margin. This form from the “QI” well (Qasim area) was assigned to *Clathrochitina* sp. by Al-Hajri (1991). It has not been included in the synonymy of *P. jacquelineae* sp. nov. in spite of its similar outline because of the occurrence of the spiny membrane also present in some *Anthochitina* species recorded in the Qusaiba-1 core hole (e.g., *Anthochitina primula* from core 15 at 145.9 ft; Plate V, 11–12). In the ISWH EW-9 well, chitinozoans with a crown of frequently bi-rooted and longer

processes (*P. sp. aff. jiangsuensis* in Paris, 1993, pl. 2, figs. 6-7) have been reported from strata assigned here to the *crassicarinata* subbiozone. They are slightly different from *P. jacquelineae* sp. nov. and are not included in the synonymy. They may represent ancestors of this new species and only the youngest specimens (cuttings from 1006 to 1070 m) reported as *P. jiangsuensis* in Paris (1993, fig. 2) are included in the synonymy. The very peculiar silhouette related to the occurrence of a crown of numerous processes is only reported in *Ancyrochitina erichseni* Sommer and Van Boekel, 1963. In the Brazilian species, however, the processes are better developed and the ratio chamber length on the neck length is different. *Plectochitina jiangsuensis* described by Geng et al. (1987) from the Llandovery of China has a similar morphology but its processes are longer and joined at their distal end by a rim. *Anthochitina primula* Nestor, 1994 from the Llandovery of Estonia has a well-developed spiny neck and a membranous rim surrounding the margin.

Range and geographic distribution: *P. jacquelineae* sp. nov. is quite abundant in the upper part of the Qusaiba Member of the Qalibah Formation in Saudi Arabia. It is restricted to core 34, at 306.0 ft, from the Baq'a-3 core hole (Fig. 8; Table 21) where it occurs with graptolites of the *turriculatus* s.l. Biozone of early Telychian age (Fig. 9). The species was also recorded in the ISWH WE-9 well (cuttings from 1006 m to 1070 m) under the name "*Pl. jiangsuensis*" but its FAD is difficult to locate precisely in this well because many specimens are likely caved. If one accepts the synonymy proposed here, *P. jacquelineae* sp. nov. is also present in the Qusaiba Member of the subsurface of the Tabuk and Qasim area (McClure, 1988).

Plectochitina lucasi sp. nov. Paris (Plate XV, 3, 7)

1993 - *Ancyrochitina* n. sp. B; Paris, pl. 2, figs. 1-2.

Derivation of the name: This species is dedicated to my grandson Lucas Paris

Holotype: Plate XV, 7, core 30, sample from 271.8 ft, IGR 72319 (T43/4).

Type locality: Baq'a-3 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 30, sample from 271.8 ft, Telychian.

Paratype: Plate XV, 3, core 30, sample from 271.8 ft, IGR 72319 (T43/1).

Material: 280 specimens were picked from the organic residues of the Baq'a-3, cores 27 to 32 (Fig. 8; Table 21); about 3500 specimens are present in the organic residues as only 10% was picked from the samples at 271.8 ft and at 250.5 ft, and 2% at 289.1 ft (see Table 3).

Diagnosis: Long *Plectochitina* species with a small flat-bottomed conical chamber; very long cylindrical neck ended by a flaring collarette; vesicle wall smooth; five to six "lyre-like" shaped processes, with multi-roots and a cell-like (vesicular) internal structure.

Description: This long chitinozoan (L ranging from 177.5 to 348 μm ; mean length: 271.6 μm ; holotype length: 254.6 μm without processes). The straight to slightly convex flanks of the thickset chamber converge rapidly toward a conspicuous flexure (chamber diameter larger than the chamber length). The vesicle wall is smooth; the polygonal pattern visible around the margin of the holotype (Plate XV, 7b) is possibly a preservation artifact only visible with SEM at high magnification. No shoulder has been observed. The long and slender neck (mean length of the neck, including the collarette: ca. 197.5 μm) gives a distinctive silhouette to this species (ratio L/lc close to 1.4). The collarette flaring around the aperture has straight to finely serrate lips. The most discriminating character concerns the five to six quite short processes developed on the rounded margin. These cell-like processes originate from a peculiar multi-rooted structure (Plate XV, 7b) composed of ca. four short proximal "roots" directly fixed to the vesicle and merging into two distinct longer branches, which join themselves into a

slender hollow process. This pattern is not visible on the paratype (Plate XV, 3) because the chamber walls hide the proximal connection of the preserved processes. The presence of these multi-rooted processes and their “spongy” to cell-like internal structure is easily visible in transmitted light microscopy. The processes have a peculiar profile with a curved short proximal part oriented at 45° with regard to the longitudinal axis of the vesicle and becoming parallel to this axis in the remaining part (“lyre-like” aspect).

Measurements (Table 12; Figs. 18a–b).

	L	Lc	Dp	Dc	Dcoll.	l. processes
Holotype	254.6	174.2	(63.6) *50.9	(26.8) **18.7	(38.5) **27.0	46.9
Mean	271.6	197.5	(73.2) *58.5	(29.2) **20.5	(41.4) **29.0	49.8
Maximum	348	281	(85.4) *68.3	(36.8) **25.8	(53.6) **37.5	80.4
Minimum	177.5	110.6	(60.3) *48.2	(23.5) **16.4	(33.5) **23.5	23.5

Table 12: Biometric data (micrometers) for *Plectochitina lucasi* sp. nov. Means are based on 36 compressed specimens from the Baq’a-3 core hole, core 30 at 271.8 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: *Plectochitina lucasi* sp. nov. is one of the numerous *Plectochitina* with multi-rooted processes. In the present case, however, the rooting is rather short and is different from the rooting of the processes of *P. alisawyahensis* sp. nov. (see above). *Ancyrochitina* species with large hollow processes (e.g. *A. fragilis* Eisenack, 1955a or *A. magna* Nestor, 1982) have

frequently longitudinal cracks near the connection of these processes on the margin. These cracks to some extent may mirror the rooting of *P. lucasi* sp. nov. Among the long-necked Silurian *Plectochitina* species, *P. clathrospinosa* (Eisenack, 1968) has wide multi-rooted processes with very short and thin distal part (an assignment to *Plectochitina* is preferred here for this species; see Table 22). The general outline of the vesicle of *A. parafragilis* Al-Hajri and Paris, 1998 from the Sharawra Member is similar to that of *A. lucasi* sp. nov. but its chamber is more pear-shaped and its robust hollow processes have no multi-rooted proximal attachment, nor a cell-like internal structure. *A. alhajrii* sp. nov. is different in that it has processes without a spongy or vesicular internal structure.

In the upper part of the Baq'a-3 core hole, fairly long-necked chitinozoans have a silhouette similar to that of *P. lucasi* sp. nov. They are identified *Plectochitina* cf. *lucasi* and are differentiated from *P. lucasi* sp. nov. by their short and slender multi-rooted processes (Plate XVIII, 1b, 2b). Moreover, granules or cones are present on their chamber and neck (Plate XVIII, 1a, 1b).

Range and geographic distribution: *P. lucasi* sp. nov. is abundant in the Baq'a-3 well from 250.5 to 289.1 ft (cores 27 to 32). It is the dominant species at 271.8 ft (63% of the recorded chitinozoans; see Fig. 8). *P. lucasi* sp. nov. is the index species of the eponymous subbiozone. This *lucasi* subbiozone is representative of the lower part of the *obtusa* Biozone referred to the Telychian (likely mid- to late Telychian; see stratigraphic discussion above, and Fig. 9). Identical chitinozoan specimens were recorded in the ISWH EW-9 well, in cutting samples from 3478 ft to 3596.3 ft (1058 m to 1094 m) (Paris, 1993; pl. 2, figs. 1-2). These specimens provisionally called *Ancyrochitina* n. sp. B by Paris (1993) are included in the synonymy list of *P. lucasi* sp. nov. The corresponding samples from the ISWH EW-9 well are assigned to the *lucasi* subbiozone and are therefore of Telychian age (Fig. 9).

Subfamily **Angochitinae** Paris, 1981

Genus ***Fungochitina*** Taugourdeau, 1966

Type species: Conochitina fungiformis Eisenack, 1931.

Fungochitina merrelli sp. nov. Paris (Plate IX, 1, 3; Plate X, 5)

? 1988 - *Sphaerochitina lepta* Jenkins, 1970; McClure, pl. VIII, figs. 11-12.

? 1991 - *Ancyochitina merga* Jenkins, 1970; Al-Hajri, pl. 30, figs.1-2, 4.

2005 - *Angochitina milleri* n. sp. nomen nudum; Paris, pl. 3, figs. 1, 3; pl. 4, figs. 5a-b.

Derivation of the name: The new specie is dedicated to Mr Merrell Miller for his long collaboration and his extensive studies on the Saudi Arabian palynomorphs.

Holotype: Plate IX, 1, core 49, sample from 450.1 ft, IGR 72340 (R45).

Type locality: Baq'a-3 core hole, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation; core 49, sample from 450.1 ft, early Telychian.

Paratypes: Plate IX, 3, core 49, sample from 450.1 ft, IGR 72340 (S45/3); Plate X, 5, core 9, sample from 450.1 ft, IGR 72340 (Q45/4).

Material: 13 specimens picked in the organic residues from cores 7 and 15 in the Baq'a-4 core hole (about 120 specimens in the remaining unpicked residues; see Table 2). 13 specimens picked in the organic residues from cores 47 to 49 in the Baq'a-3 core hole (about 43 in the remaining unpicked residues; Table 3).

Diagnosis: Small *Fungochitina* species with a flat-based conical chamber and a short cylindrical neck; conspicuous flexure; rounded margin; well-developed simple or “*lambda*-type” spines randomly arrayed on the vesicle, but longer near the margin.

Description: This small species (L ranging from ca. 94 μm to 138 μm ; mean length: 111.2 μm ; length of the holotype: 123.8 μm ; see Table 13; Figs. 19a–b) has a thickset conical chamber with walls tapering rapidly toward a conspicuous flexure. The flanks are straight (no shoulder observed). The margin is rounded but this character as well as the flat bottom may be variously modified during the compression (Plate IX, 1, 3). The cylindrical neck is short (less than half of the total vesicle length) and shows a straight to weakly serrate aperture. The flaring aspect of the neck of the specimen illustrated on Plate IX, 3 is due to its twisted and folded wall. The discriminating character is the spiny ornamentation randomly distributed on the vesicle. These spines are generally simple, but some of them have a widened proximal part or a “*lambda*-type” insertion on the vesicle wall. These tapering spines or hairs (Plate X, 5b) are quite long (maximum length up to 15 μm). This ornamentation is better developed on the margin and on the lower half of the flanks. The spines are much shorter on the neck and on the bottom of the chamber and they are simple cones near the aperture (Plate IX, 1).

Measurements (Table 13; Figs. 19a–b).

			*57.7	**18.8	**18.8	
--	--	--	-------	--------	--------	--

Table 13: Biometric data (micrometers) for *Fungochitina merrelli* sp. nov. Means are based on 13 compressed specimens from the Baq'a-3 core hole, at 450.1 ft depth and 9 specimens from the Baq'a-4 core hole core at 120.1 and 40.1 ft (raw data: between brackets; *correction factor: 0.8 ; ** correction factor: 0.7).

Discussion: *Angochitina* and *Fungochitina* genera are both spiny Lagenochitinidae, which have respectively an ovoid and a conical to lenticular chamber (Paris et al., 1999).

Fungochitina species normally have a flat bottom and a fairly sharp margin. In the present material, depending on the vesicle compression, the chamber bottom also seems flat, but this character is possibly accentuated by folding of the base into the chamber (Plate IX, 1; Plate X, 5a). The lateral compression has also accentuates the apparent width of the holotype and a coeff. of 0.7 has been used when restoring its chamber diameter (see Table 13). This small species could alternatively be attributed either to *Fungochitina* or to *Angochitina* and originally it was as a *nomen nudum* assigned to *Angochitina* because the hair-like ornamentation is more commonly observed in this genus. However, during the course of a revision of the Angochitinae, the new species *merrelli* is attributed to *Fungochitina*, in order to fit with the “compact” diagnosis of this genus in Paris et al. (1999). Al-Hajri (1991, pl. 29, figs. 2-4; pl. 30, figs. 1-2, 4) has illustrated and described specimens similar to *F. merrelli* sp. nov. Some of these specimens display longer spines on the margin (e.g. pl. 29, figs. 2-4) suggesting an assignment to *Ancyrochitina*. The two specimens from the Qusaiba Member of the Tabuk and Qasim areas illustrated by McClure (1988) under the name “*Sphaerochitina lepta*” (see synonymy) seem comparable to *F. merrelli* sp. nov. The illustration, however, does not permit a confident assignment to our new species.

The silhouette of *F. merrelli* sp. nov. is comparable with that of some Devonian *Fungochitina* species, such as *F. pilosa* (Collinson and Scott, 1958) or *F. hispida* (Taugourdeau and de Jekhosky, 1960), which have more robust spines and longer necks. *F. bernesgae* (Cramer, 1967) from the Silurian of Spain has shorter spines and a better developed neck. *F. illinoisensis* Butcher, Mikulic and Kluessendorf, 2010 from the Rhuddanian of the Illinois, USA, has a larger vesicle, more robust conical spines and a flared collarete.

In the Qusaiba-1 core hole, specimens provisionally identified as *Fungochitina?* sp. aff. *F. merrelli* sp. nov. (Fig. 6; Table 19) were recorded in core 22 at 210.9 ft (Plate III, 4a–b) and in core 15 at 145.9 ft (Plate V, 4, 8a–b). Their spiny ornamentation is more densely distributed than in the *F. merrelli* sp. nov., their ratio Dp/dc is lower and the spines seem better developed on the margin (Plate III, 4b). The last character to some extent evokes *Ancyrochitina* species (see McClure, 1988).

Range and geographic distribution: *F. merrelli* sp. nov. is recorded in the upper part of the Qusaiba Member in the Baq'a-4 and Baq'a-3 core holes (Figs. 7–8). This restricted distribution makes it suitable as the index species of the *merrelli* total-range subbiozone characterizing the upper part of the *macclurei* Biozone. The occurrence of *F. merrelli* with graptolites of the *guerichi* Biozone allows an age assignment of the corresponding strata to the early Telychian. *F. merrelli* sp. nov. is possibly represented (see synonymy above) in the Qusaiba Member of the Qalibah Formation in well “QA” of the Tabuk area (Al-Hajri, 1991; McClure, 1988).

Genus *Muscochitina* Paris, 1981

Type species: *Muscochitina muscosa* Paris, 1981

Muscochitina olivieri sp. nov. Paris (Plate I, 1, 4, 6)

v. 1991 - *Sphaerochitina* sp. indet.; Paris, pl. 1, figs. 7a-b.

v. 1992 - *Sphaerochitina* sp. indet.; Paris, fig. 6.

v. 2005 – *Muscochitina* sp. nov. 1; Paris, pl. 6, figs. 1a-b, 4a-c.

Derivation of the name: The species is dedicated to my son Olivier Chang Paris, for his help in preparing my photographic plates, drawings and databases.

Holotype: Plate I, 4, core 27, sample at 251.1 ft, IGR 72253, (O49).

Type locality: Qusaiba-1 core hole, core 27, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation, core 27, 251.1 ft, mid Aeronian (upper part of the *qusaibaensis* Biozone)

Paratype: Plate I, 1, core 27, sample at 251.1 ft, IGR 72253, (M44/1).

Material: 58 picked specimens from the organic residue of Qusaiba-1 core 27 at 251.1 ft, and about 240 additional specimens in the remaining unpicked residue (see Table 1)

Diagnosis: *Muscochitina* species with a flaring neck, well-differentiated from the ovoid to spherical chamber; vesicle covered with a mesh-like structure composed of thin threads radiating from dispersed short pillars or knobs.

Description: This medium sized *Muscochitina* species with a vesicle length (L) ranging from ca. 110 μm to 195 μm (L holotype: 147.4 μm ; mean: 140.1 μm ; see Table 14, Figs. 20a–b) has a well-developed flaring neck separated from the chamber by a conspicuous flexure. The shoulder is fairly weak as the chamber is ovoid to sub-spherical, especially when the wall is folded during the compression of the vesicle (Plate I, 4a). The neck gently flares aperturalwards, and represents one third to one half of the total vesicle length (length the neck

of the holotype: $lc= 67 \mu\text{m}$). The lips around the aperture are straight or slightly notched (Plate I, 1a). The distinctive character of this species is the peculiar elevated mesh covering the whole vesicle. This ornamentation is composed of finial structures (fleuron-like) made of thin radial threads diverging from a central connection point or knot (Plate I, 1b, 4b–c). These connection points are fixed to the vesicle wall through very short pillars fairly regularly dispersed on the vesicle. The slender threads (up to ten threads per finial structure) taper distally (Plate I, 4c). This mesh-like ornamentation fades away on the neck. The mesh may trap small particles (Plate I, 1b, 4b–c) and thus simulates a granular wall surface in transmitted light microscopy.

Measurements (Table 14; Figs. 20a–b).

	L	Lc	Dp	Dc	Dcoll.

Maximum	194.3	90.5	(87.1) *69.7	(50.3) **35.2	(53.6) **37.5
Minimum	110.6	40.2	(50.3) *40.3	(28.5) **20.0	(33.5) **23.5

Table 11: Biometric data (micrometers) for *Muscochitina olivieri* sp. nov. Means are based on 37 compressed specimens from the Qusaiba-1 core hole, core 27 at 251.1 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: *Muscochitina muscosa* Paris, 1981 has a better-developed neck and its ornamentation is made of a regularly and densely meshed network. The mesh-like

ornamentation of *Muscochitina samiri* Boumendjel, 2002 is restricted to the margin and is not arranged in finial structures. When the finial ornamentation is eroded, *M. olivieri* sp. nov. may be confused with *Sphaerochitina solitudina* Paris, 1988b as only granules corresponding to the scars of the minute pillars are preserved on the wall surface (see Plate I, 6). Because the tiny threads of the finial structures, SEM observations are required for identifying this new species.

Range and geographic distribution: In the Qusaiba-1 core hole, *Muscochitina olivieri* sp. nov. occurs in core 27, at 251.1 ft where it is abundant. Very rare specimens are also recorded in core 26 at 248.3 ft. The new species seems restricted to the upper part of the *qusaibaensis* chitinozoan biozone assigned to the mid Aeronian on graptolite evidence (*convolutus* Biozone; see discussion above). *M. olivieri* sp. nov. was also reported under the provisional name “*Sphaerochitina* sp. indet.” from core 17, at 16635.7 ft depth in the UDYN-1 well (Paris, 1991), and from core 20, at 16872 ft depth in the TINT-2 well (Paris, 1992). The occurrence of *M. olivieri* sp. nov. allows a more refined correlation of parts of these two deep wells within the mid-Aeronian.

Order **Operculatifera** Eisenack, 1972

Family **Desmochitinidae** Eisenack, 1931, emend Paris, 1981

Subfamily **Desmochitinae** Paris, 1981

Genus ***Bursachitina*** Taugourdeau, 1966

Type species: Desmochitina bursa Taugourdeau and de Jekhowsky, 1960

Bursachitina baqaensis sp. nov. Paris (Plate VIII, 3)

2005 - *Bursachitina baqaensis* nomen nudum; Paris, pl. 2, fig. 3.

Derivation of the name: from the Baq'a locality in north-western Central Saudi Arabia, where the Baq'a-4 core hole was drilled.

Holotype: Plate VIII, 3, core 19, sample at 163.0 ft, upper vesicle, IGR 72364 (O46/1).

Type locality: Baq'a-4 core hole, core 19, north-western Central Saudi Arabia

Type stratum: Qusaiba Member of the Qalibah Formation, core 19, sample at 163.0 ft, late Aeronian (upper part of the *hemeri* Biozone).

Paratype: Plate VIII, 3, core 19, 163.0 ft, lower vesicle, IGR 72364 (O46/1).

Material: 32 isolated vesicles and four connected vesicles (as two twins) from core 19, at 163.0 ft in the Baq'a-4 core hole.

Diagnosis: *Bursachitina* species with a distinct sharp margin; vesicle thick at margin and smooth; slightly convex base with a circular scar; thin collarette with finely serrate lips.

Description: The observed vesicles are perfectly smooth (the granules on the lower specimen on Plate VIII, 3 are small mineral crystals that formed during the drying of the specimen). The vesicle is rather small (L ranging from ca. 74 μm to 164 μm ; L holotype: 110.6 μm ; Dp holotype near the margin: 97.2 μm) (Table 15; Fig. 21a). The rather thickset chamber (Dp close to lp; Fig. 21b) is conical with flanks gently tapering toward the collarette. This collarette (lcoll. ranging from 10 μm to 50 μm) has membranous finely serrate lips. The imprint of the folded operculum is visible in the lower vesicle (Plate VIII, 3). It gives the original diameter of the aperture (53 μm) prior to the compression, which altered the

silhouette of the vesicle. The operculum corresponds usually to a fairly long cylindrical plug composed of a disc with a thin-walled rima (total length up to 30 μm). In specimens with a well-developed collarete, this operculum is located quite deep, near the chamber-collarete junction. In the available material, the collarete and most of the chamber are completely flattened but the fairly sharp margin, because of its thicker walls is less deformed. The differential compression due to differences in the thickness of the walls resulted in an accentuation of the convexity of the flanks (normally straight or slightly convex). As a consequence the wider part of the chamber is no longer on the margin (its original position before this differential compression) but moved towards the middle part of the chamber. The chamber bottom is slightly convex, but the original convexity is accentuated during the compression that caused the tear near the central callus of the lower vesicle (Plate VIII, 3). The callus has a wide rim (diameter close to 20 μm) surrounding a slightly depressed area. *Measurements* (Table 15; Figs. 21a–b).

	L	lp	lcoll.	Dp	Dcoll.
Holotype	110.6	83.8	24.5	(97.2) *77.8	(60.3) **42.2
Mean	113.6	85.1	30.0	(92.2) *73.8	(60.4) **42.3
Maximum	164.0	137.4	50.3	(120.6) *96.5	99.2 **69.5
Minimum	73.7	57.0	10.1	(73.7) *59.0	(45.6) **32.0

Table 15: Biometric data (micrometers) for *Bursachitina baqaensis* sp. nov. Means are based on 36 flattened specimens from the Ba'qa-4 core hole, core 19, at 163.0 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: The length of the chamber (lp: vesicle length minus the well-developed collarete) of this new species is close to its width (mean ratio lp/Dp: 0.92 but approximately 1.15 when the flattening is corrected; see Table 15 and Fig. 21b). This leads to its assignment to the genus *Bursachitina* as *Euconochitina* has a lp/Dp ratio exceeding one. Only a few specimens with an unusually short collarete with regard to the chamber length have been recorded (see Fig. 21b). *B. pachygaster* (Taugourdeau, 1963), *B. lagenicula* Eisenack, 1971 and *B. concava* Eisenack, 1972 have sigmoid flanks and the two latter have a rounded margin. *B. bursa* (Taugourdeau and de Jekhowsky, 1960) and *B. timpaniformis* Tsegelnjuk, 1982 have a more thickset vesicle. The vesicle of *B. nana* (Nestor, 1994) from the early Silurian of Estonia is smaller.

Range and geographic distribution: *Bursachitina baqaensis* sp. nov. is only recorded in the Qusaiba Member in the Baq'a-4 well. It is rare at 180.4 ft (core 21) but more abundant at 160.0 ft (core 19). The corresponding samples are bracketed between strata yielding graptolites respectively of the *convolutus* and of the *guerichi* Zones. Consequently, they are referred to the late Aeronian (see Fig. 9).

Subfamily **Cutichitinae** Achab, Asselin and Soufiane, 1993

Genus *Cutichitina* Achab, Asselin and Soufiane, 1993

Type species: *Cutichitina legrandi* Achab, Asselin and Soufiane, 1993

Cutichitina minivelata sp. nov. Paris (Plate III, 9; Plate VI, 12)

- ? 1988 - *Pterochitina? perivelata* (Eisenack, 1937); McClure, pl. VI, fig. 8.
- ? 1988 - *Hoegisphaera complanata* (Eisenack, 1932); McClure, pl. VI, fig. 13 (non fig. 12).
- 1991 - *Pterochitina deichaii* Taugourdeau, 1963; Al-Hajri, pl. 38, figs. 2-3, (non fig. 6).
- v. 1992 - *Calpichitina cf. densa* Eisenack, 1962; Paris, pl. 1, fig. 5.
- v. 2003 - *Calpichitina* n. sp. 1 (spongy); Paris, pl. 1, 12a-b; pl. 4, fig. 9.
- v. 2005 - *Pterochitina deichaii* Taugourdeau, 1963; Paris, pl. 3, fig. 5.

Derivation of the name: The name refers to the short velum that covers the vesicle.

Holotype: Plate III, 9 (second vesicle from the top), core 24, sample at 228.8 ft, IGR 72264 (S46/1).

Type locality: Qusaiba-1 core hole, core 24, North Central Saudi Arabia.

Type stratum: Qusaiba Member of the Qalibah Formation, core 24, at 228.8 ft, mid-Aeronian (*alargada* Biozone)

Paratypes: Plate III, 9 (vesicles other than the holotype in the chain-like structure), core 24, at 228.8 ft, IGR 72264 (S46/4).

Material: Several hundred vesicles, mostly in chain-like structures with up to fifty connected vesicles in cores 14 to 27 from the Qusaiba-1 core hole (Fig. 6; Table 19) and in cores 21 to 40 from the Baq'a-3 core hole (Fig. 8; Table 21); several hundred additional specimens, mostly in chain-like structures, were recorded in the TINT-2 and UDYN-1 wells.

Diagnosis: Small lenticular to thickset barrel-like vesicle without neck or collarette; felt-like to spongy membrane (velum) encapsulating the chamber; wide aperture with flat operculum; chain-like structure with resistant inter-vesicle connections.

Description: This very small chitinozoan (mean vesicle length close to 63 μm) has a lenticular chamber with rounded flanks and rather flat apertural and antiapertural surfaces. It usually

occurs in long chain-like structures compressed laterally (Plate III, 9; Plate VI, 12). In that case, each vesicle looks like a very thickset barrel (L/D_p close to 0.5; see Table 16 and Fig. 22a). Important variations of the size and of the shape of the vesicles are noticed between different chain-like structures. This is obvious on Figure 22a where the four chain-like structures used for the measurements appear as separate clusters. A slight difference is also recorded along each “chain” as illustrated on Figure 22b (see also Plate VI, 12a). Closer connected individuals occur at one extremity of the chain whereas the larger and better-separated vesicles are at the end. This suggests that these chain-like structures correspond to early stages of a lay out (likely intra-oviduct connected ovules, according to the interpretation given by Paris and Nölvak, 1999). No neck or collarete are present around the large aperture with a diameter about half size of the chamber, and which is closed by a discoid operculum (Plate III, 9). The antiapertural and apertural poles are usually difficult to identify because the folding and the buckling of the chamber hide the aperture in the catenary structures. The latter are extremely common in the recovered organic residues and indicate a strong intra-vesicle linkage. One of the distinctive features of this species is the spongy to felt-like outer layer extending laterally when the vesicles are totally flattened. This character is more visible in transmitted light microscopy. When the vesicles are severely compressed laterally, this unstuck thin-walled layer wraps the chamber and appears as a less opaque area surrounding chamber walls, especially along the flanks. This fairly transparent zone (only outer layer involved) can be shifted on one side of the vesicle during the compression and in that case it may be easily confused with the carina of a *Pterochitina* species (see discussion below).

Measurements (Table 16; Figs. 22a–b).

	L	Dp	l.“sleeve”
Holotype	33.5	57.0	6.7

		*45.6	
Mean	63.1	(93.6) *74.7	10.5
Maximum	57.0	(124.0) *99.2	20.1
Minimum	28.5	(57.0) *45.6	5.1

Table 16: Biometric data (micrometers) for *Cutichitina minivelata* sp. nov. Means are based on 53 compressed specimens from the Qusaiba-1 core hole, core 24 at 228.8 ft and core 14 at 136.5 ft depth (raw data: between brackets; *correction factor: 0.8).

Discussion: It may be tempting to assign the specimens recovered in core samples from the Qusaiba-1 and Baq'a-3 core holes either to *Pterochitina* or to *Calpichitina*, as these two genera have also a lenticular chamber (Paris et al., 1999). An extensive discussion of *Cutichitina* and *Pterochitina*, which may be easily confused when the vesicle are compressed, is given by Paris in Rickards et al (2010, p. 115). Concerning the Qusaiba material, the three-dimensional reconstruction of the flattened vesicles leads to a preferred assignment to *Cutichitina* Achab, Asselin and Soufiane, 1993, even if this genus was created for the Desmochitinidae with an ovoid chamber (so far no genus has been created for the chitinozoans with a lenticular chamber surrounded by a detached velum). In all likelihood *Cutichitina minivelata* sp. nov. has been confused (see synonymy) with *P. deichaii* as their total-range overlaps. SEM observations prove that the specimens of *P. deichaii* (e. g., Plate II, 3a–b; Plate XVI, 8) associated with *C. minivelata* sp. nov. in the Qusaiba-1 core hole have a different flattening pattern, and display a disk-like aspect when flattened and even buckled (Plate II, 3a–b). The specimen illustrated by McClure (1988, pl. VI, fig. 13) as *H. complanata*

may be a *C. minivelata* sp. nov. compressed laterally as some spongy remains seem present on the flanks. The specimen tentatively referred to *P. perivelata* by McClure (1988, pl. VI, fig. 8) is axially compressed and is surrounded by a spongy structure recalling that of *C. minivelata* sp. nov. Some specimens are puzzling such as the three vesicles illustrated on Plate IX, 5 and assigned to *P. deichaii*. They have a spongy surface but in transmitted light microscopy, a carina is visible on the lower vesicle, which shows in addition a short collarete around a narrow aperture.

C. minivelata sp. nov. is abundant in core 17 from the UDYN-1 well and in cores 18-20 from TINT-2 well (see synonymy) where it was provisionally referred to *Calpichitina* cf. *densa* (Paris, 1991,1992). *Calpichitina* Wilson and Hedlund, 1964 was indeed an alternative generic assignment for the Qusaiba specimens because their lenticular chamber (see synonymy list). Moreover, *Calpichitina* may have a spongy surface, e.g., *C. spongiloricata* (Wrona, 1980) but no completely separated membrane is reported in this genus. Other *Calpichitina* species have partly folded outer layer, e.g. *C. squamosa* (Laufeld, 1974) from the Ludlow of Gotland, or *C. velata* (Wrona, 1980), from the upper Silurian of Poland. Both species have a membranous collarete and are not commonly arranged in resistant chain-like structures like *Cutichitina minivelata* sp. nov. The specimen recorded in the Baq'a-3 core hole at 350.0 ft (Plate XIII, 6) has a spongy outer layer stuck on the chamber. It is tentatively assigned to *Cutichitina minivelata* sp. nov.

Range and geographic distribution: *Cutichitina minivelata* sp. nov. is a rather long ranging species, which is irregularly distributed in the Qusaiba Member of the Qalibah Formation in the Qusaiba-1 and in the Baq'a-3 core holes (Figs. 6 and 8). The corresponding strata are assigned to the Aeronian and to the Telychian *pro parte*. Based on the proposed synonymy, the new species is most likely present in the Qusaiba Member of the Qalibah Formation in the subsurface of the Qasim area in samples 6a and 7a from the "QU" well (Al-Hajri, 1991). *C.*

minivelata sp. nov. is abundant in the upper part of core 17 from the UDYN-1 well and in cores 17 to 20 in the TINT-2 well (Paris, 1991, 1992). Based on the present calibration of the chitinozoans of the Qusaiba Member by graptolites (Zalasiewicz et al., 2007), the corresponding strata are assigned to the mid-Aeronian to early Telychian (Fig. 9).

Subfamily **Pterochitiniinae** Paris, 1981

Genus *Armoricochitina* Paris, 1981

Type species: Linochitina ? ceneratiensis Paris, 1976.

Armoricochitina crassicarinata sp. nov. Paris (Plate XI, 2; Plate XII, 2, 6; Plate XIV, 7)

1988 - *Linochitina cingulata* (Eisenack, 1937); McClure, pl. VII, fig. 2.

? 1991 - *Armoricochitina nigerica* (Bouché, 1965); Al-Hajri, pl. 26, figs. 1-2, 4 (non fig. 3).

1993 - *Armoricochitina* ? n. sp. A; Paris, pl. 2, figs. 4-5.

2005 - *Armoricochitina crassicarinata* nomen nudum; Paris pl. 5, 2; pl. 6, figs. 2, 6; pl. fig. 7.

Derivation of the name: the name refers to the thickness (Latin “*crassus*” for thick) of the carina.

Holotype: Plate XII, 2; core 40, sample from 370.4 ft, IGR 72332 (S48/1).

Type locality: Baq’a-3 core hole, core 40, north-western Central Saudi Arabia

Type stratum: Qusaiba Member of the Qalibah Formation, core 40, 370.4 ft, early Telychian (upper part of the *macclurei* Biozone).

Paratypes: Plate XII, 6; core 40, sample from 370.4 ft, IGR 72332 (Q48/2).

Material: 166 picked vesicles from the organic residues from the Baq'a-3 cores 36 to 45 (Fig. 8; Table 21) and several hundred specimens in the corresponding unpicked organic residues (see Table 3).

Diagnosis: Small *Armoricochitina* species with a thick-walled ovoid chamber; weakly corrugated walls; short membranous collarete; thickened carina below the margin.

Description: This species shares all the characters of the genus *Armoricochitina*. The ovoid to pear-shaped chamber has a slightly convex bottom but this aspect is frequently hidden when the bottom wall is folded inwards the chamber in laterally compressed vesicles. The larger diameter is situated over the lower third of the chamber. The chamber width (Dp) represents about three quarter of the vesicle length (L) (Fig. 23a; mean L/Dp is close to 1.35; L/Dp of the holotype=1.26). The vesicle wall is quite thick (ca. 3 μm ; the thickness is measured on the lower vesicle on Plate XII, 6). Its surface shows a corrugated pattern (minute depressions; see Plate XI, 2b) fading away toward the aperture. The flat discoid operculum is located at the base of a thin-walled cylindrical (Plate XII, 6) to gently flaring collarete (Plate XII, 2). The variable development of the collarete (up to 82.5 μm length) intervenes in the general silhouette of the vesicle, especially in the few longer individuals recorded (Table 17, Fig. 23b). The most discriminating character is the thick and very short carina (mean length about 3.5 μm) located just below the margin (Plate XII, 2; Plate XIV, 7). The carina has a rounded distal border and may look like a rim (Plate XI, 2b). Occasionally, some "twins" have been observed (inter-vesicle linkage by simple juxtaposition; see, Plate XII, 6). A small scar exists on the apex of the vesicle.

Measurements (Table 17; Figs. 23a–b).

	L	lcoll.	Dp	dcoll.	l carina

Holotype	117.3	23.5	(93.2) *74.6	(60.3) **42.3	3.5
Mean	123.6	33.0	(91.9) *73.5	(57.7) **40.4	3.5
Maximum	198.0	82.5	(120.6) *96.5	(80.4) **56.3	6.7
Minimum	83.8	6.7	(57.0) *45.6	(43.6) **30.5	1.7

Table 17: Biometric data (micrometers) for *Armoricochitina crassicarinata* sp. nov. Means are based on 45 compressed specimens from the Ba'qa-3 core hole, core 40 at 370.4 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: As frequently observed in *Armoricochitina* species (e.g. *A. nigerica*; see Paris et al., this volume), significant intraspecific morphological variations are noticed in the recovered populations of *A. crassicarinata* sp. nov. These variations concern mainly the length of the collarete (Fig. 23b). They may also implicate the development of the carina (slightly longer or thinner in some specimens) and the degree of curving of the sigmoid flanks. This curving may modify significantly the outline of the vesicles (e.g., holotype on Plate XII, 2, versus paratype, Plate XII, 6). The resulting variable morphologies are regarded as simple intraspecific fluctuations as no trend through time is observed.

Only a few other *Armoricochitina* have been described. Compared to *A. crassicarinata* sp. nov., *A. nigerica* (Bouché, 1965) from the Late Ordovician of northern Gondwana has a better-developed membranous carina and bears small granules on its wall (see Paris et al., this volume). *A. armoricana* (Rauscher and Doubinger, 1967) is a Darriwilian species with a more

slender vesicle and a better developed carina. *A. ceneratiensis* (Paris, 1976) from the Lower Devonian of Brittany has a more ovoid chamber and smooth walls.

In the Baq'a-3 well, a few specimens with a long neck/collarete are provisionally referred to *A. cf. crassicarinata* sp. nov. (Plate XIII, 7) as they may be end members of a polymorphic population (Figs. 23a–b). To some extents, the silhouette of *A. cf. crassicarinata* sp. nov. (Plate XIII, 7) is reminiscent of those of *A. armoricana* (Rauscher and Doubinger, 1967) or of *A. granulifera* Nölvak and Grahn, 1993. *A. crassicarinata* sp. nov. is distinguished from *A. gengi* sp. nov. by its thick rim-like carina (see discussion of *A. gengi* sp. nov. below).

Some *Armoricochitina* illustrated by Al-Hajri (1991, pl. 26, figs. 1-2, 4) from the Tabuk area (sample 9 from well "QA") have a short and fairly thick carina similar to that of *A. crassicarinata* sp. nov. They are therefore tentatively included in its synonymy list (see above).

Range and geographic distribution: *A. crassicarinata* sp. nov. may be abundant in the Qusaiba Member of the Qalibah Formation in the Baq'a-3 core hole (24% of the recorded chitinozoans at 350.1 ft; Fig. 8). In this well it ranges at least over 78.3 ft (23.8 m) from core 36 to core 45 and likely more as there is ca. 23 ft (7 m) separating these cores from the closest ones devoid of *A. crassicarinata* sp. nov. (Fig. 8; Table 21). This new species is selected as the index species of a subbiozone characterizing the upper part of the *macclurei* Biozone. This *crassicarinata* subbiozone is assigned to the early Telychian as the corresponding strata yield graptolites of the *turriculatus* Biozone (Fig. 9; see discussion above).

If one accepts the synonymy proposed here, *A. crassicarinata* sp. nov. occurs in cutting samples of the ISWH EW. 9 well from 3517.4 ft to 3602.9 ft (1070 m to 1096 m) (Paris, 1993). In this well, it is the dominating species in the core samples at 3594.7 ft to 3609.5 ft. (1093.5 m to 1098 m), which therefore have an early Telychian age.

The new species is probably also present in the Qusaiba Member of the Qalibah Formation in

the subsurface of the Tabuk area (sample 9 from well “QA”).

Armoricochitina gengi sp. nov. Paris (Plate XV, 1; Plate XVIII, 5)

1993 - *Armoricochitina* n. sp. aff. *A. panzuda* (Cramer, 1964); Paris, pl. 2, fig. 3.

1988 - *Cyathochitina* sp.; McClure, pl. VII, fig. 11.

Derivation of the name: this new species is dedicated to Professor Geng Liang-Yu (Nanjing, China) for his impressive work on the Silurian chitinozoans from China.

Holotype: Plate XV, 1; core 27, sample from 250.5 ft, IGR 72316 (S45/1).

Type locality: Baq'a-3 core hole, core 27, at 250.5 ft, north-western Central Saudi Arabia

Type stratum: Qusaiba Member of the Qalibah Formation, core 27, at 250.5 ft, Telychian (*obtusa* Biozone).

Material: Sixteen picked specimens from the organic residue from 250.5 ft (core 27) and 62 specimens from 150.4 ft (core 16) in the Baq'a-3 core hole (Table 3, Fig. 8); about 600 specimens in the corresponding unpicked organic residues.

Diagnosis: *Armoricochitina* species with a conical to pear-shaped chamber; walls fairly thick with a weakly corrugate surface; membranous carina located closely below the margin; chamber bottom gently convex.

Description: This new species has gently tapering flanks with an inflexion of their convergence over the middle part of the chamber. Because important variations in the development of the neck/collarete (lcoll. is measured from this inflexion to the border of the lips; Table 18; Fig. 24b), the total length of the vesicle (L) shows greater variations than the chamber width (Table 18; Fig. 24a). The sigmoid profile of the flanks may be deeply

modified by differential compression of the vesicle. When totally flattened (Plate XV, 1), the maximum width of the chamber fits with the margin, whereas when the lower part of the chamber is not totally flattened the maximum width is situated at the lower fourth or fifth of the vesicle length (Plate XVIII, 5). The surface of the rather thick chamber wall displays small corrugations generating a “wavy” pattern more or less parallel to the margin. The thickness of the chamber wall (ca. 2.5 μm) is visible on lateral cracks of the compressed holotype (Plate XV, 1). A membranous collarete with straight lips surrounds the aperture. The chamber bottom is slightly convex but this character may be modified when the bottom wall is folded into the chamber in compressed vesicles. A membranous carina (mean length ca. 13 μm) is located just below the margin. This critical taxonomical character is sometime difficult to evaluate on compressed specimens, e.g. the holotype (Plate XV, 1), or when the carina is folded up on the margin (Plate XVIII, 5). A circular scar (not visible on the illustrated material) occurs on the bottom of the chamber.

Table 18: Biometric data (micrometers) for *Armoricochitina gengi* sp. nov. Means are based on 16 compressed specimens from the Ba'qa-3 core hole, core 27 at 250.5 ft depth (raw data: between brackets; *correction factor: 0.8; ** correction factor: 0.7).

Discussion: An assignment to the genus *Armoricochitina* rather than to *Cingulochitina* is preferred because the widest part of the chamber is above the margin. In addition, the chamber wall is fairly thick and displays micro-corrugations. Both are features uncommon in *Cingulochitina* species.

A. gengi sp. nov. is similar to *A. crassicarinata* sp. nov., but the latter has a distinct thick rim-like carina. *A. panzuda* (Cramer, 1964) from the Emsian of northern Gondwana regions (Paris et al., 2000) has a carina located well below the margin. *A. gengi* sp. nov. resembles several Silurian *Cingulochitina* species with a short carina. *C. burdinalensis* Verniers, 1999 and *C. bouniensis* Verniers, 1999 have a more ovoid chamber. *C. serrata* (Taugourdeau and de Jekhowsky, 1960) has a smooth wall, a more convex chamber bottom and a mucron.

The chitinozoan “chain” recorded at 350.1 ft in the Baq'a-3 well, and provisionally identified *Armoricochitina?* sp. (Plate XIII, 2) possibly represents teratologic specimens (thickset vesicles) of *A. gengi* sp. nov.

Other individuals, possibly belonging to this new species, are provisionally identified *Armoricochitina* cf. *gengi* sp. nov. (Plate XVII, 1–2) because the characteristic features, i.e. the membranous carina or the corrugated wall surface are less obvious (Plate XVII: 1a, 2a). The large circular rim on their convex bottom (Plate XVII, 1b, 2b) suggests that they were usually arranged in chain-like structures such as the “twins recorded” at 350.5 ft (Plate XIII, 2).

Range and geographic distribution: In the Baq'a-3 core hole, *A. gengi* sp. nov. is recorded in the upper part of the Qusaiba Member of the Qalibah Formation from core 27 to core 16

where it is more common (Fig. 8; Table 21). The species ranges through the *obtusa* and the *silurica* biozones, which are referred to the Telychian (see Fig. 9 and the stratigraphical discussion above).

A. gengi sp. nov. is very rare and irregularly represented in the ISWH EW-9 well. It was provisionally called “*Armoricochitina* n. sp. aff. *panzuda*” (see synonymy) and occurs in cutting samples from 3254.5 ft to 3576.6 ft (990 m to 1088 m) (Paris, 1993).

Acknowledgements

The authors thank the Saudi Arabian Ministry of Petroleum and Mineral Resources and the Saudi Arabian Oil Company (Saudi Aramco) for granting permission to publish this paper.

They also thank very warmly Bernard Owens who initiated the very first steps of this CIMP/Aramco research project.

Olivier Chang Paris prepared the plates and the figures of this paper and organised the repository of the palynological slides and the loading of the relate material in databases.

The authors are grateful to the two reviewers, Antony Butcher (Portsmouth University, UK) and Jacques Verniers, (Ghent University, Belgium), for valuable remarks and comments.

Captions of tables 1-3 and 19-22 (N. B. Captions of Tables 4 to 18 are already introduced in the text)

Note to the editor: in order to fulfil the requests of the chief editor, tables 1-3 are removed from the main text and introduced in Appendix A. Because the lettering was too small in the stratabug diagrams, they are replaced by classical palynological diagrams (Figs. 6-8) and the corresponding staratbug diagrams are transferred in a new Appendix C as Table 19 to Table 21. As a consequence, the former “Table 19” is transferred in a new Appendix D as Table 22.

Table 1. Data concerning the lithology, the processing, and the faunal content of the core samples processed in the Silurian part of the Qusaiba-1 core hole.

Table 2. Data concerning the lithology, the processing, and the faunal content of the core samples processed in the Baq'a-4 core hole.

Table 3. Data concerning the lithology, the processing, and the faunal content of the core samples processed in the Baq'a-3 core hole.

Table 19. Chitinozoans of the early Rhuddanian and mid-Aeronian samples from the Qusaiba Member of the Qusaiba-1 core hole plotted on a stratabug diagram. The author(s) and the year of publication of the recorded chitinozoans taxa are given on Table 22.

Table 20. Chitinozoans of the mid-Aeronian and early Telychian samples from the Qusaiba Member of the Baq'a-4 core hole plotted on a stratabug diagram. The author(s) and the year of publication of the recorded chitinozoans taxa are given on Table 22.

Table 21. Chitinozoans of the Telychian samples from the Qusaiba Member of the Baq'a-3 core hole plotted on a stratabug diagram. The author(s) and the year of publication of the recorded chitinozoans taxa are given on Table 22.

Table 22. List of the chitinozoan taxa recorded in the Qusaiba-1, Baq'a-3 and Baq'a-4 core holes. The chitinozoan species cited in the text but not present in the studied material have an asterisk.

Captions of the figures

Figs. 1a-c. Location map showing the study areas in Saudi Arabia (1a) and the position of the previously studied wells. (1b) location of the Qusaiba-1 core hole, (1c) location of the Baq'a-3 and Baq'a-4 core holes (modified from Zalasiewicz et al., 2007).

Fig. 2. Lithostratigraphy, and Early Palaeozoic stratigraphic nomenclature in Saudi Arabia (modified from Miller and Melvin, 2005; Melvin, this volume). (generalized lithology: sand dominated in yellow; shale dominated in brown).

Fig. 3. Lithological column and location of the studied core samples in the early Silurian Qusaiba Member of the Qalibah Formation in the Qusaiba-1 core hole. (lithology: sand dominated in yellow; shale dominated in brown).

Fig. 4. Location of the studied core samples in the early Silurian Qusaiba Member of the

Qalibah Formation in the Baq'a-4 core hole. (lithology: shale dominated in brown).

Fig. 5. Location of the studied core samples in the early Silurian Qusaiba Member of the

Qalibah Formation in the Baq'a-3 core hole. (lithology: shale dominated in brown).

Fig. 6. Biozonation, ranges and abundances of the chitinozoans recorded in the early

Rhuddanian and in the mid-Aeronian samples from the Qusaiba Member of the

Qusaiba-1 core hole. The author(s) and the year of publication of the recorded

chitinozoans taxa are given on Table 22.

Fig. 7. Biozonation, ranges and abundances of the chitinozoans recorded in the mid-Aeronian

and early Telychian samples from the Qusaiba Member of the Baq'a-4 core hole. The

author(s) and the year of publication of the recorded chitinozoans taxa are given on

Table 22.

Fig. 8. Biozonation, ranges and abundances of the chitinozoans recorded in the Telychian

samples from the Qusaiba Member of the Baq'a-3 core hole. The author(s) and the year

of publication of the recorded chitinozoans taxa are given on Table 22.

Fig. 9. Chitinozoan biozones and subbiozones identified in the Qusaiba-1, Baq'a-4 and Baq'a-

3 core holes. Correlation with the ISWH EW-9, and age assignments with regard to the

early Silurian graptolite zonation (Zalasiewicz et al., 2007, 2009) and to the standard

Silurian chronostratigraphy with the same colour code as in Figures 6-8.

Figs. 10a–b. Cross plots of the measurements of *Conochitina viiuae* sp. nov. Paris from the Qusaiba-1 core hole, core 26, at 245.8 ft. 10a: the chamber diameter (D_p) plotted against the vesicle length (L); 10b: the chamber diameter (D_p) plotted against the neck diameter (D_c). The compression affecting the diameter of the chamber and of the neck is not corrected for. (Holotype: red diamond).

Figs. 11a–b. Cross plots of the measurements of *Spinachitina geerti* sp. nov. Paris from the Ba'qa-4 core hole, core 28, at 240.7 ft. 11a: the chamber diameter (D_p) plotted against the vesicle length (L); 11b: vesicle length (L) plotted against the chamber length (l_p). The compression affecting the chamber diameter is not corrected (Holotype: red diamond).

Fig. 12. Cross plots of the measurements of *Cyathochitina neolatipatagium* sp. nov. Paris from the Qusaiba-1 core hole, core 14, 136.5 ft and 133.35 ft. The chamber diameter (D_p) is plotted against the carina width (l carina). (Holotype: red diamond).

Figs. 13a–b. Cross plots of the measurements of *Ancyrochitina alhajrii* sp. nov. Paris from the Baq'a-3 core hole, core 47, at 441.7 ft. 13a: vesicle length (L) plotted against the neck length (l_c); 13b: the chamber diameter (D_p) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 14a–b. Cross plots of the measurements of *Ancyrochitina camilleae* sp. nov. Paris from the Baq'a-4, core 19, at 163.0 ft. 14a: vesicle length (L) plotted against the chamber diameter (D_p); 14b: the processes length (l proc.) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 15a–b. Cross plots of the measurements of *Plectochitina alisawyahensis* sp. nov. Paris from the Ba'qa-3 core hole, core 40 at 370.4 ft, and core 49 at 450.1 ft. 15a: vesicle length (L) plotted against the neck length (lc); 15b: the processes length (l proc.) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 16a–b. Cross plots of the measurements of *Plectochitina alnaimi* sp. nov. Paris from the Qusaiba-1 core hole, core 14 at 140.1 ft. 16a: vesicle length (L) plotted against the chamber diameter (Dp); 16b: the neck length (lc) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 17a–b. Cross plots of the measurements of *Plectochitina jacquelineae* sp. nov. Paris from the Baq'a-3 core hole, core 34 at 306.0 ft. 17a: vesicle length (L) plotted against the neck length (lc); 17b: the chamber diameter (Dp) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 18a–b. Cross plots of the measurements of *Plectochitina lucasi* sp. nov. Paris from the Baq'a-3 core hole, core 30 at 271.8 ft depth. 18a: vesicle length (L) plotted against the chamber diameter (Dp); 18b: the neck length (lc) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 19a–b. Cross plots of the measurements of *Fungochitina merrelli* sp. nov. Paris from the Baq'a-3 core hole, at 450.1 ft depth, and 9 specimens from the Baq'a-4 core hole core at 120.1 and 40.1 ft depth. 19a: vesicle length (L) plotted against the chamber diameter

(Dp); 19b: the neck length (lc) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 20a–b. Cross plots of the measurements of *Muscochitina olivieri* sp. nov. Paris from the Baq'a-3, core 27, sample from 251.1 ft. 20a: vesicle length (L) plotted against the chamber diameter (Dp); 20b: the neck length (lc) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 21a–b. Cross plots of the measurements of *Bursachitina baqaensis* sp. nov. Paris from the Baq'a-4, core 19, sample from 163.0 ft. 21a: vesicle length (L) plotted against the chamber diameter (Dp); 21b: the chamber diameter (Dp) plotted against the chamber length (lp). (Holotype: red diamond).

Figs. 22a–b. Cross plots of the measurements of *Cutichitina minivelata* sp. nov. Paris from the Baq'a-3, core 24, sample from 228.8 ft and core 14 at 136.5 ft. 22a: vesicle length (L) plotted against the chamber diameter (Dp); 22b: vesicle length (L) plotted against the chamber diameter (Dp) in a one chain-like structure. (Holotype: red diamond).

Figs. 23a–b. Cross plots of the measurements of *Armoricochitina crassicarinata* sp. nov. Paris from the Baq'a-3, core 40, sample from 370.4 ft. 23a: vesicle length (L) plotted against the chamber diameter (Dp); 23b: the collarette/neck length (lcoll.) plotted against the vesicle length (L). (Holotype: red diamond).

Figs. 24a–b. Cross plots of the measurements of *Armoricochitina gengi* sp. nov. Paris from the Baq'a-3, core 27, sample from 250.5 ft. 24a: vesicle length (L) plotted against the

chamber diameter (D_p); 24b: the vesicle length (L) plotted against the neck/collarete length ($l_{coll.}$). (Holotype: red diamond).

Plate captions

Plate I. Mid-Aeronian chitinozoans (upper *qusaibaensis* Biozone) from the Qusaiba-1 core hole. Scale bar represents 100 micrometers, except for 1b, 3b, 4b, 4c, 5b, 6b and 8 (10 micrometers).

- 1, 4, 6. *Muscochitina olivieri* sp. nov. 251.10 ft. (1): paratype, IGR 72253, (M44/1). (4): holotype, IGR 72253, (O49). (1b, 4b–c): note the very peculiar ornamentation composed of finial structures with thin filaments connecting the tips of granule-shaped pillars. (6): IGR 72253 (Q44/2). This specimen is assigned to *Muscochitina olivieri* sp. nov. in spite the thin filaments connecting granule-shaped pillars are eroded.
2. *Conochitina viiuae* sp. nov. 251.10 ft; IGR 72253 (M44). In this totally compressed vesicle, the tilted chamber bottom hides the mucron.
- 3, 9. *Conochitina elongata* Taugourdeau, 1963. 251.10 ft. (3a): IGR 72253 (M47/1). Note the thickened rim corresponding to the margin. (9): IGR 72253 (O45).
5. *Angochitina qusaibaensis* Paris and Al-Hajri, 1995. 251.10 ft; IGR 72253 (Q44). Possibly a new form with a long slender neck acting as a transitional form between *A. qusaibaensis* and "true" *A. hemeri*. The prosome of these specimens is prolonged by a thin walled tubular structure (see also Plate II, 6–9).

7. *Plectochitina pseudoagglutinans* (Taugourdeau, 1963). 251.10 ft; IGR 72253 (P46/4).
8. *Conochitina edjelensis* Taugourdeau, 1963. 251.10 ft; IGR 72253 (O45/2).

Plate II. Mid-Aeronian chitinozoans (upper *quasibaensis* Biozone) from the Qusaiba-1 core. Scale bar represents 100 micrometers, except for 3b, 4b, 6b and 9 (10 micrometers).

- 1–2. *Cyathochitina caputoi* Da Costa, 1971. 245.80 ft. (1): IGR 72256 (P43). (2): IGR 72256 (R43/4).
3. *Pterochitina deichaii* Taugourdeau, 1963. 245.80 ft; IGR 72256 (Q43). Detail of a catenary structure showing the modification of the general shape of the vesicle after compression. Note the peculiar operculum with radial "ribs" around the central circular scar corresponding to the inter-vesicle connection.
- 4–5. *Conochitina viiuae* sp. nov. 245.80 ft. (4): paratype, IGR 72256 (O44/3), note the elongate vesicle with a constriction, and (4b) the protruding mucron. (5) holotype, IGR 72256 (M44/4).
- 6–9. *Angochitina qusaibaensis* Paris and Al-Hajri, 1995. These represent possibly a new long and slender-necked transitional form between typical *A. qusaibaensis* and *A. hemeri*. 245.80 ft. (6): IGR 72256 (P47/4). (7): IGR 72256 (P47/4). (8): IGR 72256 (R48). (9): IGR 72256 (R47/4). The prosome of these specimens is extended by an extruded thin-walled tubular structure at least as long as the vesicle itself. (6b, 9): close-up of the lips surrounding this structure.
10. *Plectochitina* cf. *P. alnaimi* sp. nov. 245.80 ft; IGR 72256 (R47) (lost specimen). Note the serrate aperture.

Plate III. Mid-Aeronian chitinozoans (*alargada* Biozone) from the Qusaiba-1 core hole.

Scale bar represents 100 micrometers, except for 2b, 3b, 4b, 10b and 11 (10 micrometers).

- 1–2. *Conochitina* sp. 210.90 ft. (1): IGR 72270 (P46). (2a): IGR 72270 (Q47/1). (2b): detail of the mucron with a central pit.
3. *Belonechitina paravitrea* Paris and Al-Hajri, 1995. 210.90 ft; IGR 72270 (O43/2).
4. *Fungochitina* ? sp. aff. *F. merrelli* sp. nov. 210.90 ft. (4): IGR 72270 (N42/2); (4b): note the crown of simple to bi-rooted, very short processes around the margin.
5. *Calpichitina* sp. aff. *densa* (Eisenack, 1962). 210.90 ft; IGR 72270 (O44/1).
Catenary structure with the operculum of one vesicle still fixed to the apex of the neighbouring vesicle.
6. *Plectochitina alnaimi* sp. nov. 210.90 ft, IGR 72270 (Q42/3).
- 7–8. *Plectochitina pseudoagglutinans* (Taugourdeau, 1963). (7): 210.90 ft IGR 72270 (S42/1). (8): 228.80 ft; IGR 72264 (P43/3).
9. *Cutichitina minivelata* sp. nov. 228.80 ft; IGR 72264 (S46/1). The holotype is the second vesicle (note the tilted disc-like operculum); the paratypes are the seven other vesicles of the chain-like structure.
10. *Angochitina qusaibaensis*? Paris and Al-Hajri, 1995. 228.80 ft; IGR 72264 (R48/3). (10a) This puzzling specimen shares some characters with *A. hemeri* and *A. macclurei*. (10b) Note the progressive change from a granular ornamentation on the flanks to a more spiny ornamentation near the margin.

11. *Pterochitina deichaii* Taugourdeau, 1963. 228.80 ft; IGR 72270 (S48). Three dimensional vesicle with the carina near the equator of the chamber and the small disc-like operculum.

Plate IV. Mid-Aeronian chitinozoans (*hemeri* Biozone) from the Qusaiba-1 core hole.

Scale bar represents 100 micrometers, except for 5b (10 micrometers).

1. *Cyathochitina caputoi* Da Costa, 1971. 167.70 ft; IGR 722782 (P38/2); (1a): note the short carina with rounded borders.
- 2–4. *Conochitina* gr. *armillata* Taugourdeau and de Jekhowsky, 1960. (2a): 167.70 ft; IGR 722782 (N40), note the three connected vesicles, the widened chamber of the species, and the mucron. (3): 167.70 ft IGR 722782 (P43/1). (4): 176.05 ft; IGR 72279 (R45/3).
- 5–6. *Angochitina hemeri* Paris and Al-Hajri, 1995. 176.05 ft. (5a): IGR 72279 (T46/2). (5b): note the well-developed spines on the chamber. (6): IGR 72279 (Q46/4).
- 7–8. *Plectochitina paraguayensis* Wood and Miller, 1991. 176.05 ft. (7): IGR 72279 (Q49/4). (8): IGR 72279 (S49), note the very long processes (close to 250 micrometers length).
9. *Plectochitina alnaimi* sp. nov. 176.05 ft; IGR 72279 (R47).

Plate V. Aeronian chitinozoans (*hemeri* Biozone) from the Qusaiba-1 core hole. Scale bar represents 100 micrometers, except for 2–3, 6, 8b and 13b (10 micrometers).

1. *Angochitina hemeri* Paris and Al-Hajri, 1995. 140.10 ft; IGR 72291 (N42). Very elongate specimen with eroded ornamentation (spines preserved only in a fold of the chamber).
- 2, 10. *Plectochitina alnaimi* sp. nov. (2): holotype, 140.10 ft; IGR 72291 (Q42); note the "lambda-type" processes. (10): paratype, core sample from 150.80 ft; ; IGR 72286 (R44).
- 3, 11–12. *Anthochitina primula* Nestor, 1994. 145.90 ft. (3): IGR 72288, close up showing the serrate membranous rim located along the margin. (11): IGR 72288 (P42), well-developed membranous serrate rim around the margin. (12): IGR 72288 (O43), partly compressed specimen with a tilted bottom.
4. *Fungochitina?* sp. aff. *F. merrelli* sp. nov. 145.90 ft, IGR 72288 (O42/4), anti-apertural view showing short spines on the chamber bottom.
- 5, 9. *Plectochitina paraguayensis* Wood and Miller, 1991. (5): 145.90 ft.; IGR 72288 (S45): long processes possibly connected at their distal end. (9): core sample from 150.80 ft; IGR 72286 (P43/4).
6. *Plectochitina* cf. *clathrospinoso* (Eisenack, 1968). 145.90 ft; IGR 72288 (Q47), specimen with a tilted bottom showing the peculiar rooting pattern of the processes.
7. *Conochitina* gr. *armillata* Taugourdeau and de Jekhowsky, 1960. 145.90 ft; IGR 72288 (N44). Note the presence of a mucron, and the inverted orientation of these stuck vesicles.
8. *Fungochitina ?* sp. aff. *F. merrelli* sp. nov. 145.90 ft; IGR 72288 (R44/2). (8a) Note the densely distributed well-developed spines on the chamber, and the longer spines (often of "lambda-type") surrounding the margin (8b).

13. *Belonechitina paravitrea* Paris and Al-Hajri, 1995. 150.80 ft; IGR 72286 (P41/2).
(13a) Note the thinness of the wall, and the random and scarce minute spines concentrated close to the margin (13b).

Plate VI. Aeronian chitinozoans (*hemeri* Biozone) from the Qusaiba-1 core hole. Scale bar represents 100 micrometers, except for 3b and 5 (10 micrometers).

- 1–2. *Linochitina* ? sp. 132.05 ft. (1): IGR 72299 (N44/3). (2): IGR 72299 (O43). These connected specimens show vesicle outline and a connection pattern identical to those of *Linochitina* Eisenack, 1968 emend Paris, 1981. Because the tubular copula has not been seen, these specimens could also belong to *Euconochitina*. They are therefore provisionally kept in open nomenclature.
3. *Angochitina hemeri* Paris and Al-Hajri, 1995. 132.05 ft. (3a): IGR 72299 (S43/2). (3b): note the partially eroded spines on the chamber similar to the ornamentation of *A. qusaibaensis* Paris and Al-Hajri, 1995.
- 4–5. *Belonechitina arabiensis* Paris and Al-Hajri, 1995. 133.45 ft. (4): IGR 72298 (P50/3). (5): IGR 72298 (P50/1), specimen with unusually densely and well-developed spines (possibly a different species).
6. *Plectochitina* sp. 132.05 ft; IGR 72299 (S45/2). Note long cell-like processes with simple branching at their half length.
- 7–8, 11. *Cyathochitina neolatipatagium* sp. nov. (7): paratype, 133.45 ft; IGR 72298 (Q50). (8): holotype, 136.50 ft; IGR 72293 (Q40/4). (11): paratype, IGR 72293 (Q40). Note the thickened rim around the margin, and the large carina.
9. *Ancyrochitina* gr. *ancyrea* (Eisenack 1931. 134.20 ft; IGR 72296 (P44/4).

10. *Calpichitina* sp. aff. *densa* (Eisenack, 1962). 134.20 ft; IGR 72296 (N46/4). Folded and compressed chain-like structure. The large disc-like operculum surrounded by a short lip is visible on the second vesicle on the right side.
12. *Cutichitina minivelata* sp. nov. 136.50 ft; IGR 72293 (N40). (12a): compressed catenary structure showing a morphological differentiation in the curved part of the chain (poorly separated and smaller vesicles). (12b): close up of the upper part of the chain showing the spongy outer layer "extruded" laterally during the lateral compression of the chain-like structure.

Plate VII. Aeronian and early Telychian chitinozoans (*hemeri* and *macclurei* biozones) from the Baq'a-4 core hole. Scale bar represents 100 micrometers, except for 3b, 7b and 8 (10 micrometers).

- 1, 4–5, 7–8. *Spinachitina geerti* sp. nov. Core 28, sample from 240.7 ft. Note the large range in vesicle silhouette, and the short spines randomly distributed on the chamber. (1): paratype, IGR 72371 (Q42/1). (4): paratype, IGR 72371 (Q41/2). (5): atypical specimen with a very short sub-conical vesicle, IGR 72371 (O42/2). (7a): holotype, IGR 72371 (P42/4) and detail of the spines on its margin (7b). (8): paratype, IGR 72371 (Q41), detail of the long spines on the margin.
- 2-3. *Angochitina macclurei* Paris and Al-Hajri, 1995. (2) core 7, sample from 40.1 ft; IGR 72351 (N44/3). The specimen is shorter than typical *A. macclurei* but the short spines are present on the chamber and on the neck. (3a): core 28, sample from 240.7 ft, IGR 72371 (P39/2). (3b): note the short spines on the chamber and on the neck.
6. *Plectochitina pseudoagglutinans* (Taugourdeau, 1963). Core 7, sample from 40.1 ft;

IGR 72351 (O47/1). Note long processes and the blunt spines on the chamber and on the neck.

Plate VIII. Aeronian and early Telychian chitinozoans (*hemeri* and *macclurei* biozones) from the Baq'a-4 core hole. Scale bar represents 100 micrometers, except for 2b (10 micrometers).

- 1, 6. *Ancyrochitina camilleae* sp. nov. Core 19, sample from 163.0 ft. Note the short vesicle and the long and slender processes branching several times distally. (1): holotype, IGR 72364 (P41/4). (6): paratype, IGR 72364 (P44).
2. *Spinachitina* cf. *geerti* sp. nov. Core 19, sample from 163.0 ft; IGR 72364 (N43). Note the short blunt spines densely distributed along the margin. (2b): minute tubercles occur on the lower part of the chamber (eroded spines?).
3. *Bursachitina baqaensis* sp. nov. Core 19, sample from 163.0 ft IGR 72364 (O46/1). Twins showing the sharp margin; the upper vesicle is the holotype, and the lower a paratype.
4. *Conochitina* cf. *alargada* Cramer, 1967. Core 19, sample from 163.0 ft; IGR 72364 (N44/4).
- 5, 8. *Belonechitina paravitrea* Paris and Al-Hajri, 1995. Core 19, sample from 163.0 ft. (5): IGR 72364 (N45/4). (8): IGR 72364 (N44), specimen shorter than the type material.
7. *Calpichitina densa* (Eisenack, 1962). Core 7, sample from 40.7 ft; IGR 72351 (M45/3).

Plate IX. Early Telychian chitinozoans (*macclurei* Biozone) from the Baq'a-3 core hole. Scale bar represents 100 micrometers, except for 2b and 7 (10 micrometers).

- 1, 3. *Fungochitina merrelli* sp. nov. Core 49, sample from 450.1 ft. (1): holotype, IGR 72340 (R45), densely distributed spiny ornamentation extending on the neck. (3): paratype, IGR 72340 (S45/3); “*lambda*-based” spines on the chamber and on the neck; the spines around the margin are probably partly destroyed.
2. *Angochitina macclurei* Paris and Al-Hajri, 1995. Core 49, sample from 450.1 ft. (2a): IGR 72340 (U44). (2b): close up of the spiny ornamentation with cones ended by a slender spine.
- 4, 6. *Plectochitina alisawyahensis* sp. nov. Core 49, sample from 450.1 ft. (4): IGR 72340 (P43), specimen with few processes connected at their distal end with a rim. (6): IGR 72340 (T43/2), specimen in lateral view showing the racket-like arrangement of the sets of processes.
5. *Pterochitina deichaii* Taugourdeau, 1963. Core 49, sample from 450.1 ft; IGR 72340 (O43/4). Chain compressed perpendicular to the vesicle equator.
7. *Plectochitina alisawyahensis* sp. nov. Core 49, sample from 450.1 ft; IGR 72340 (R41). Close up of the random spines on the flexure.

Plate X. Early Telychian chitinozoans (*macclurei* Biozone) from the Baq’a-3 core hole. Scale bar represents 100 micrometers, except for 2b, 3a–b, 4b and 5b (10 micrometers).

1. *Angochitina macclurei* Paris and Al-Hajri, 1995. Core 47, sample from 431.7 ft; IGR 72339 (Q45/3), cluster of compressed individuals with a fairly short neck.
- 2, 4. *Ancyrochitina alhajrii* sp. nov. Core 47, sample from 431.7 ft. (2a): paratype, IGR 72339 (O40) with minute spines on the wall (2b). (4a): holotype, IGR 72339 (O45),

note the long processes, and the minute spines (length is less than 10 micrometers and their diameter less than 1 micrometer) randomly distributed on the chamber and on the base of the neck (4b).

3. *Angochitina macclurei* Paris and Al-Hajri, 1995. Core 47, sample from 431.7 ft. (3a): IGR 72339 (M43/2), three-dimensional vesicle showing the original spherical chamber. (3b): detail of the short thickset spines.
5. *Fungochitina merrelli* sp. nov. Core 49, sample from 450.1 ft. (5a): paratype, IGR 72340 (Q45/4); note the slender spines on the chamber; (5b): spines with *lambda* proximal ends and exceeding 10 micrometers length.

Plate XI. Early Telychian chitinozoans (*macclurei* Biozone) from the Baq'a-3 core hole. Scale bar represents 100 micrometers, except for 1b and 2b (10 micrometers).

1. *Angochitina macclurei* Paris and Al-Hajri, 1995. (1a) Core 42, sample from 388.0 ft; IGR 72335 (N46/4), short form; (1b): detail of the short conical spines.
2. *Armoricochitina crassicarinata* sp. nov. Core 40, sample from 370.4 ft. (2a): IGR 72332 (N44/4), distorted specimen with an unusually wide margin. (2b): detail of the slightly wrinkled surface and of the thick, but short, carina looking like a rim on the margin.
3. *Plectochitina paraguayensis* Wood and Miller, 1991. Core 42, sample from 388.0 ft; IGR 72335 (Q50).
4. *Plectochitina alisawyahensis* sp. nov. (4) Core 42, sample from 388.0 ft; IGR 72335 (O48/3). Note the blunt spines on the neck.
5. *Plectochitina* sp. aff. *alisawyahensis* sp. nov. Core 42, sample from 388.0 ft; IGR

72335 (R50/2). Note the bi-rooted processes and their branching distally.

6. *Ancyrochitina alhajrii* sp. nov. Core 47, sample from 431.7 ft; IGR 72339 (L43/4), the apparent branching of one of the processes is an artifact (organic fragment stuck on it).
7. Transitional form between *Plectochitina longicornis* (Taugourdeau and de Jekhowsky, 1960) and *Plectochitina paraguayensis* Wood and Miller, 1991. Core 42, sample from 388.0 ft; IGR 72335 (P48/1). This specimen has broad processes, recalling those of *P. paraguayensis*. The latter species, except its holotype, has a shorter neck and a more ovoid chamber.

Plate XII. Early Telychian chitinozoans (*macclurei* Biozone) from the Baq'a-3 core hole.

Scale bar represents 100 micrometers, except for 5b and 7b (10 micrometers).

1. *Ancyrochitina aculeata* Taugourdeau and de Jekhowsky, 1960. Core 38, sample from 350.1 ft; IGR 72329 (O48/1), granules on the chamber (scars of spines?) and the larger spines on the neck.
- 2, 6. *Armoricochitina crassicarinata* sp. nov. Core 40, sample from 370.4 ft. (2): holotype, IGR 72332 (S48/1), finely wrinkled chamber surface (micro-corrugations) and thickened rim below the margin; (6): paratype, IGR 72332 (Q48/2), twins showing the type of inter-vesicle linkage.
3. *Plectochitina* cf. *alisawyahensis* sp. nov. Core 40, sample from 370.4 ft; IGR 72332 (Q47).
- 4–5. *Angochitina macclurei* Paris and Al-Hajri, 1995. (4): core 40, sample from 370.4 ft, typical specimens with a spherical chamber and a neck length close to / or exceeding 3 times the chamber length, IGR 72332 (P49). (5a): core 40, sample from 370.4 ft, IGR

72332 (O44); (5b): typical spines on the chamber (hemispherical to ovoid base extending into a thin spine).

7. *Plectochitina alisawyahensis* sp. nov. Core 40, sample from 370.4 ft; IGR 72332 (P44/3). Holotype, note the “eye” (ring-structure) at mid-length of some processes, and the distal linkage of the processes with a rim.
8. *Calpichitina densa* (Eisenack 1962). Core 40, sample from 370.4 ft; IGR 72332 (R46). (8a): these specimens arranged in chain-like structure show folding of the outer layer of their operculum (8b) in relation with the flattening of the vesicles. This form seems to announce the first appearance of the genus *Margachitina* (i.e., *M. banwyensis* Mullins, 2000).

Plate XIII. Early Telychian chitinozoans (*macclurei* and *obtusa* biozones) from the Baq’a-3 core hole. Scale bar represents 100 micrometers, except for 4b, 6b and 7b (10 micrometers).

1. *Angochitina macclurei* Paris and Al-Hajri, 1995. Core 38, sample from 350.1 ft; IGR 72329 (N46); typical specimen (spherical chamber and a neck length close to 3 times the chamber length).
2. *Armoricochitina* ? sp. Core 38, sample from 350.1 ft; IGR 72329 (P46/1). These connected very short vesicles are possibly teratologic individuals of *A. genji* sp. nov. or the very first representative of the genus *Cingulochitina*.
3. *Calpichitina densa* (Eisenack, 1962). Core 38, sample from 350.1 ft; IGR 72329 (R47/3).
- 4–5. *Tanuchitina obtusa* (Taugourdeau and de Jekhowsky, 1960). Core 38, sample from 350.1 ft. (4a): IGR 72329 (R47); (4b): detail of the carina. (5): IGR 72329 (M48/4).

6. *Cutichitina* cf. *minivelata* sp. nov. (6a) core 38, sample from 350.1 ft. IGR 72329 (O48/3); (6b): the spongy outer layer is still partly stuck on the chamber of this questionable specimen compressed along the vesicle axis.
7. *Armoricochitina* cf. *crassicarinata* sp. nov. Core 38, sample from 350.1 ft; IGR 72329 (Q47). This elongate specimen separates from the other representatives of the species by its flexure and by a better-developed neck/collarete. (7b): close up of the micro-corrugations and of the carina.
8. *Ancyrochitina aculeata* Taugourdeau and de Jekhowsky, 1960. Core 38, sample from 350.1 ft; IGR 72329 (Q49); large spines on the neck and on the upper part of the chamber.

Plate XIV. Early Telychian chitinozoans (*macclurei* and *obtusa* biozones) from the Baq'a-3 core hole. Scale bar represents 100 micrometers, except for 1b, 4b, and 6b (10 micrometers).

- 1, 5. *Angochitina macclurei* Paris and Al Hajri, 1995. Core 34, sample at 306.0 ft; (1a): IGR 72323 (N45). (5): IGR 72323 (O45/3), short specimen.
2. *Ancyrochitina aculeata* Taugourdeau and de Jekhowsky, 1960. Core 34, sample at 306.0 ft; IGR 72323 (R43). Atypical specimen with an elongate neck and only granules on the chamber.
3. *Cyathochitina* gr. *caputoi* Da Costa 1971. Core 34, sample at 306.0 ft; IGR 72323 (N45/1), this specimen referred to the *caputoi* complex is one of the ultimate *Cyathochitina* recorded in the Qusaiba Member.
- 4, 6. *Plectochitina jacquelineae* sp. nov. Core 34, sample at 306.0 ft. (4a): paratype, IGR 72323 (R43); (4b): close up showing the crown of blunt short spines (ca. 10

micrometers) extending from a very short carina. (6a): holotype, IGR 72323 (P43), specimen with spines directly erected on the margin; (6b): close up of the spines, which may have a very short branching distal end.

7. *Armoricochitina crassicarinata* sp. nov. Core 38, sample from 350.1 ft; IGR 72329 (Q45/4).

Plate XV. Early Telychian chitinozoans (*obtusa* Biozone) from the Baq'a-3 core hole. Scale bar represents 100 micrometers, except for 7b and 8 (10 micrometers).

1. *Armoricochitina gengi* sp. nov. Core 27, sample from 250.5 ft. Holotype, IGR 72316 (S45/1), well-developed membranous carina (up to 20 micrometers) and the micro-corrugations on the chamber.
2. *Spinachitina* sp. Core 27, sample from 250.5 ft; IGR 72316 (R41/2), long sub-cylindrical chitinozoan carrying a crown of very short spines on its margin.
- 3, 7. *Plectochitina lucasi* sp. nov. Core 30, sample from 271.8 ft. (3): paratype, IGR 72319 (T43/1). (7a): holotype, IGR 72319 (T43/4), (7b) detail of the bi-rooted processes of the holotype.
- 4–5, 8–9. *Plectochitina alisawyahensis* sp. nov. Core 30, sample from 271.8 ft. Various patterns of connection of the processes. (4): paratype, IGR 72319 (Q45/3). (5): paratype, IGR 72319 (R45); (8): paratype, IGR 72319 (R45/1), detail of connections in a “buckle-like” set of processes.
6. *Plectochitina* cf. *alisawyahensis* sp. nov. Core 30, sample from 271.8 ft; IGR 72319 (Q45). This chitinozoan with a membranous carina extending into processes likely represents atypical *Plectochitina alisawyahensis* sp. nov. with broken processes.

9. *Plectochitina alisawyahensis* sp. nov. Core 28, sample from 250.5 ft; paratype, IGR 72316 (R41/1), apertural view showing three sets of processes; in each set, the processes are connected through their tips.

Plate XVI. Early Telychian chitinozoans (*obtusa* Biozone) from the Baq'a-3 core hole.

Scale bar represents 100 micrometers.

- 1, 3, 9. *Ancyrochitina* cf. *aculeata* Taugourdeau and de Jekhowsky, 1960. Core 27, sample from 250.5 ft. (1): IGR 72316 (O45), short form with serrate lips ending a short flaring neck. (3): IGR 72316 (N42/2). (9): IGR 72316 (S45).
2. *Armoricochitina* cf. *genji* sp. nov. Core 21, sample from 192.5 ft; IGR 72310 (P36/4). The outline of this specimen recalls those of *Conochitina elongata*. However, the thickened rim running below the margin constitutes a true carina.
4. *Conochitina elongata* Taugourdeau, 1963. Core 27, sample from 250.5 ft; IGR 72316 (P42). Note the rim corresponding to the thickened margin.
5. *Plectochitina paraguayensis* Wood and Miller, 1991. Core 27, sample from 250.5 ft; IGR 72316 (Q45). This morphotype with broad processes and a rather short neck (length of the chamber close to the length of the neck) is regarded here as typical for this species (= *P. paraguayensis* form A in Paris, 1993).
6. *Tanuchitina obtusa* (Taugourdeau and de Jekhowsky, 1960). Core 27, sample from 250.5 ft; IGR 72316 (R46/2).
7. *Plectochitina longicornis* (Taugourdeau and de Jekhowsky, 1960). Core 27, sample from 250.5 ft; IGR 72316 (O42). This species with very long and slender processes (up to two times the vesicle length) and a well-developed cylindrical neck has been

identified previously as *Plectochitina paraguayensis* form B in Paris (1993).

8. *Pterochitina deichaii* Taugourdeau, 1963. Core 21, sample from 192.5 ft; IGR 72310 (O42/3). Chain of three buckled and flattened vesicles.

Plate XVII. Early Telychian chitinozoans from the Baq'a-3 core hole. Scale bar represents 100 micrometers, except for 1b, 2b and 6 (10 microns).

1. *Armoricochitina cf. gengi* sp. nov. Core 16, sample from 150.4 ft; IGR 72304 (N42/3). The widened chamber results from its partial flattening. (1b): large protruding apical structure composed of a large rim surrounding a flat area and a small central pit.
2. *Armoricochitina cf. gengi* sp. nov. Core 18, sample from 170.9 ft; IGR 72307 (R40/1). This specimen recalls some short *Tanuchitina* species (see discussion in the Systematic section).
- 3–5. *Fungochitina* ? sp. Core 18, sample from 170.9 ft. A crown of robust cones occurs on the margin; smaller cones are randomly dispersed on the fungiform chamber and on the neck of these specimens. (3): IGR 72307 (O41), three dimensional fungiform chamber; (4): IGR 72316 (Q38/4) (5): IGR 72316 (P40/2).
- 6, 8. *Calpichitina cf. acollaris* (Eisenack 1959). Core 18, sample from 170.9 ft. (6): vesicle in antiapertural view, IGR 72307 (O39/4). (8): IGR 72307 (O40), operculum within the chamber; this specimen is significantly smaller than the Baltic species.
7. *Plectochitina* sp. Core 21, sample from 192.5 ft; IGR 72310 (Q41/1).

Plate XVIII. Early Telychian chitinozoans (*silurica* Biozone) from the Baq'a-3 core hole.

Scale bar represents 100 micrometers, except for 1b and 2b (10 micrometers).

- 1–2. *Plectochitina* cf. *lucasi* sp. nov. Core 14, sample from 130.0 ft. (1a): IGR 72302 (P46), (1b): processes with bi-rooted proximal parts. (2a): IGR 72302 (P48), slender vesicle; most of the granules on the vesicle wall are artefacts; (2b): detail of the bi-rooted processes.
- 3–4. *Euconochitina silurica* (Taugourdeau, 1963). Core 14, sample from 130.0 ft. (3): IGR 72302 (Q49/3), small vesicle with slightly serrate lips. (4): IGR 72302 (R44/4), partly compressed vesicle with an “extruded” bottom showing an apical mark. N.B. *Conochitina oelandica* subsp. *silurica* defined by Taugourdeau (1963, p. 134-137) is raised here to specific level.
5. *Armoricochitina gengi* sp. nov. Core 16, sample from 150.4 ft; IGR 72304 (O45), membranous carina folded and stuck above the margin.
6. *Tanuchitina obtusa* (Taugourdeau and de Jekhowsky, 1960). Core 16, sample from 150.4 ft; IGR 72304 (Q43), slender and gently tapering conical vesicle; less cylindrical than *T. cylindrica* (Taugourdeau and de Jekhowsky, 1960).
7. *Plectochitina* sp. aff. *alisawyahensis* sp. nov. Core 16, sample from 150.4 ft; IGR 72307 (N42), specimen tentatively referred to *P. alisawyahensis* because of its general outline and the size of its spongy processes.
8. *Ancyrochitina aculeata* Taugourdeau and de Jekhowsky, 1960. Core 16, sample from 150.4 ft; IGR 72307 (N41/4).

Table 1

Qusaiba-1 (core numbers)													SEM	Lithology of the processed material	
Sample depth (feet)	Number of chitinozoans /gram of rock	Tribolites	Lingulids	Brachiopods (articulated)	Eurypterids	Ostracodes	Scolecodonts	Graptolites rhabdosoms	Amorphous organic matter	Graphite	Pyrite	Weight of processed rock sample (grams)			Sorted chitinozoans per sample (%)
14	132.05	209			X		X					5	100	X	Green shale and micaceous siltstone with sandy laminae
14	133.45	380			X				X	X		5	100	X	Grey-greenish siltstone and shale
14	134.20	1260							XXX			5	2	X	Grey-greenish siltstone and shale
14	136.50	3080						X	X	XXX		5	2	X	Grey-greenish siltstone (chitinozoans on the bedding plane)
14	140.10	3920						X	XXX			5	2	X	Grey-greenish shale (chitinozoans on the bedding plane)
15	145.90	2590							XXX			5	10	X	Greenish shale
16	150.80	580						X				5	10	X	Greenish shale
17	159.15	1470	X					X			X	5	10		Greenish shale
18	167.70	3780	X				X	XX	XXX		X	5	1	X	Greenish shale
18	171.30	1374										5	10		Grey-geenish shale
19	176.05	1172						XX				5	10	X	Grey-geenish shale (chitinozoans on the bedding plane)
19	180.10	1536	X					XX				5	10		Grey-geenish shale (chitinozoans on the bedding plane)
