HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

The competitive impacts of global SST warming

and CO2 increase on Sahelian rainfall: results from CMIP5 idealized simulations

Background

West Africa is affected by large climate variability at different timescales, from interannual to multidecadal, with consequent strong environmental and socio-economic impacts, especially in the Sahelian countries, where the economy is mainly sustained by rainfed agriculture. The annual precipitation in the Sahel is limited to the boreal summer season, from July to September (JAS), and it is strongly linked to the West African monsoon (WAM) dynamics. After a wet period during the 50s-60s, Sahel has undergone a severe (large scale and long-lasting) drought in the 70s-80s, and a partial recovery of precipitation is observed at the turn of the 21st century.

Objective

- To study the effects of CO2 concentration increase and global SST warming on the WAM variability in July-September (JAS);
- focusing on the regional-versus-global aspects of the WAM dynamics and drivers.

Motivation

A number of studies tackled the problem of the simulation and interpretation of the climate variability and change in the Sahel, pointing out the importance of the global SST variability and GHG concentrations, which produce opposite effects on the monsoonal precipitation. A consensus exists on the drying effect of the global SST, and the positive effect of the increasing GHG concentration, which appear therefore in competition. In this context, state-of-the-art coupled climate models still show poor ability in correctly simulating the WAM historical variability and also a large spread is observed in future climate projections.

| Experiment | Forcing | |
|------------|---|----------------------------|
| | SST | CO2 |
| CTL | Observed 1979-2008 | Observed 1979-2008 |
| 4 K | Observed 1979-2008 + uniform 4 K increase | Observed 1979-2008 |
| 4xCO2 | Observed 1979-2008 | 4x increased concentration |

Conclusions

Competition between the global SST warming and the CO2 increase in driving the WAM variability:

SST warming -> Dry Sahel

(reinforced evaporation in the global Tropics -> reduced MSE meridional gradient over West Africa - > inhibition of the monsoonal flow and the ITCZ northward migration);

CO2 increase -> Wet Sahel

(atmospheric radiative warming -> enhanced evaporation over the Sahel and warmer Sahara ->reinforced MSE meridional gradient -> more intense monsoonal circulation and precipitation).

- ! Comprehension of the mechanisms linking the WAM variability to SST and CO2 forcings;
- ! Ability of the climate models in reproducing these mechanisms, for reliable simulations of the past, present and future variability.
