## Campaign overview and measurements: TRAQA (June-July 2012) – SAFMED (July 2013)

## Spatial and vertical distribution of pollution aerosols in the western Mediterranean

### Elevated levels of background pollution throughout the western basin

- Pollution aerosol layers measured up to a distance of ~250 km from the coastline
- Aerosol layers are distributed ubiquitously
- The aerosol concentrations are comparable to those measured in continental urban areas

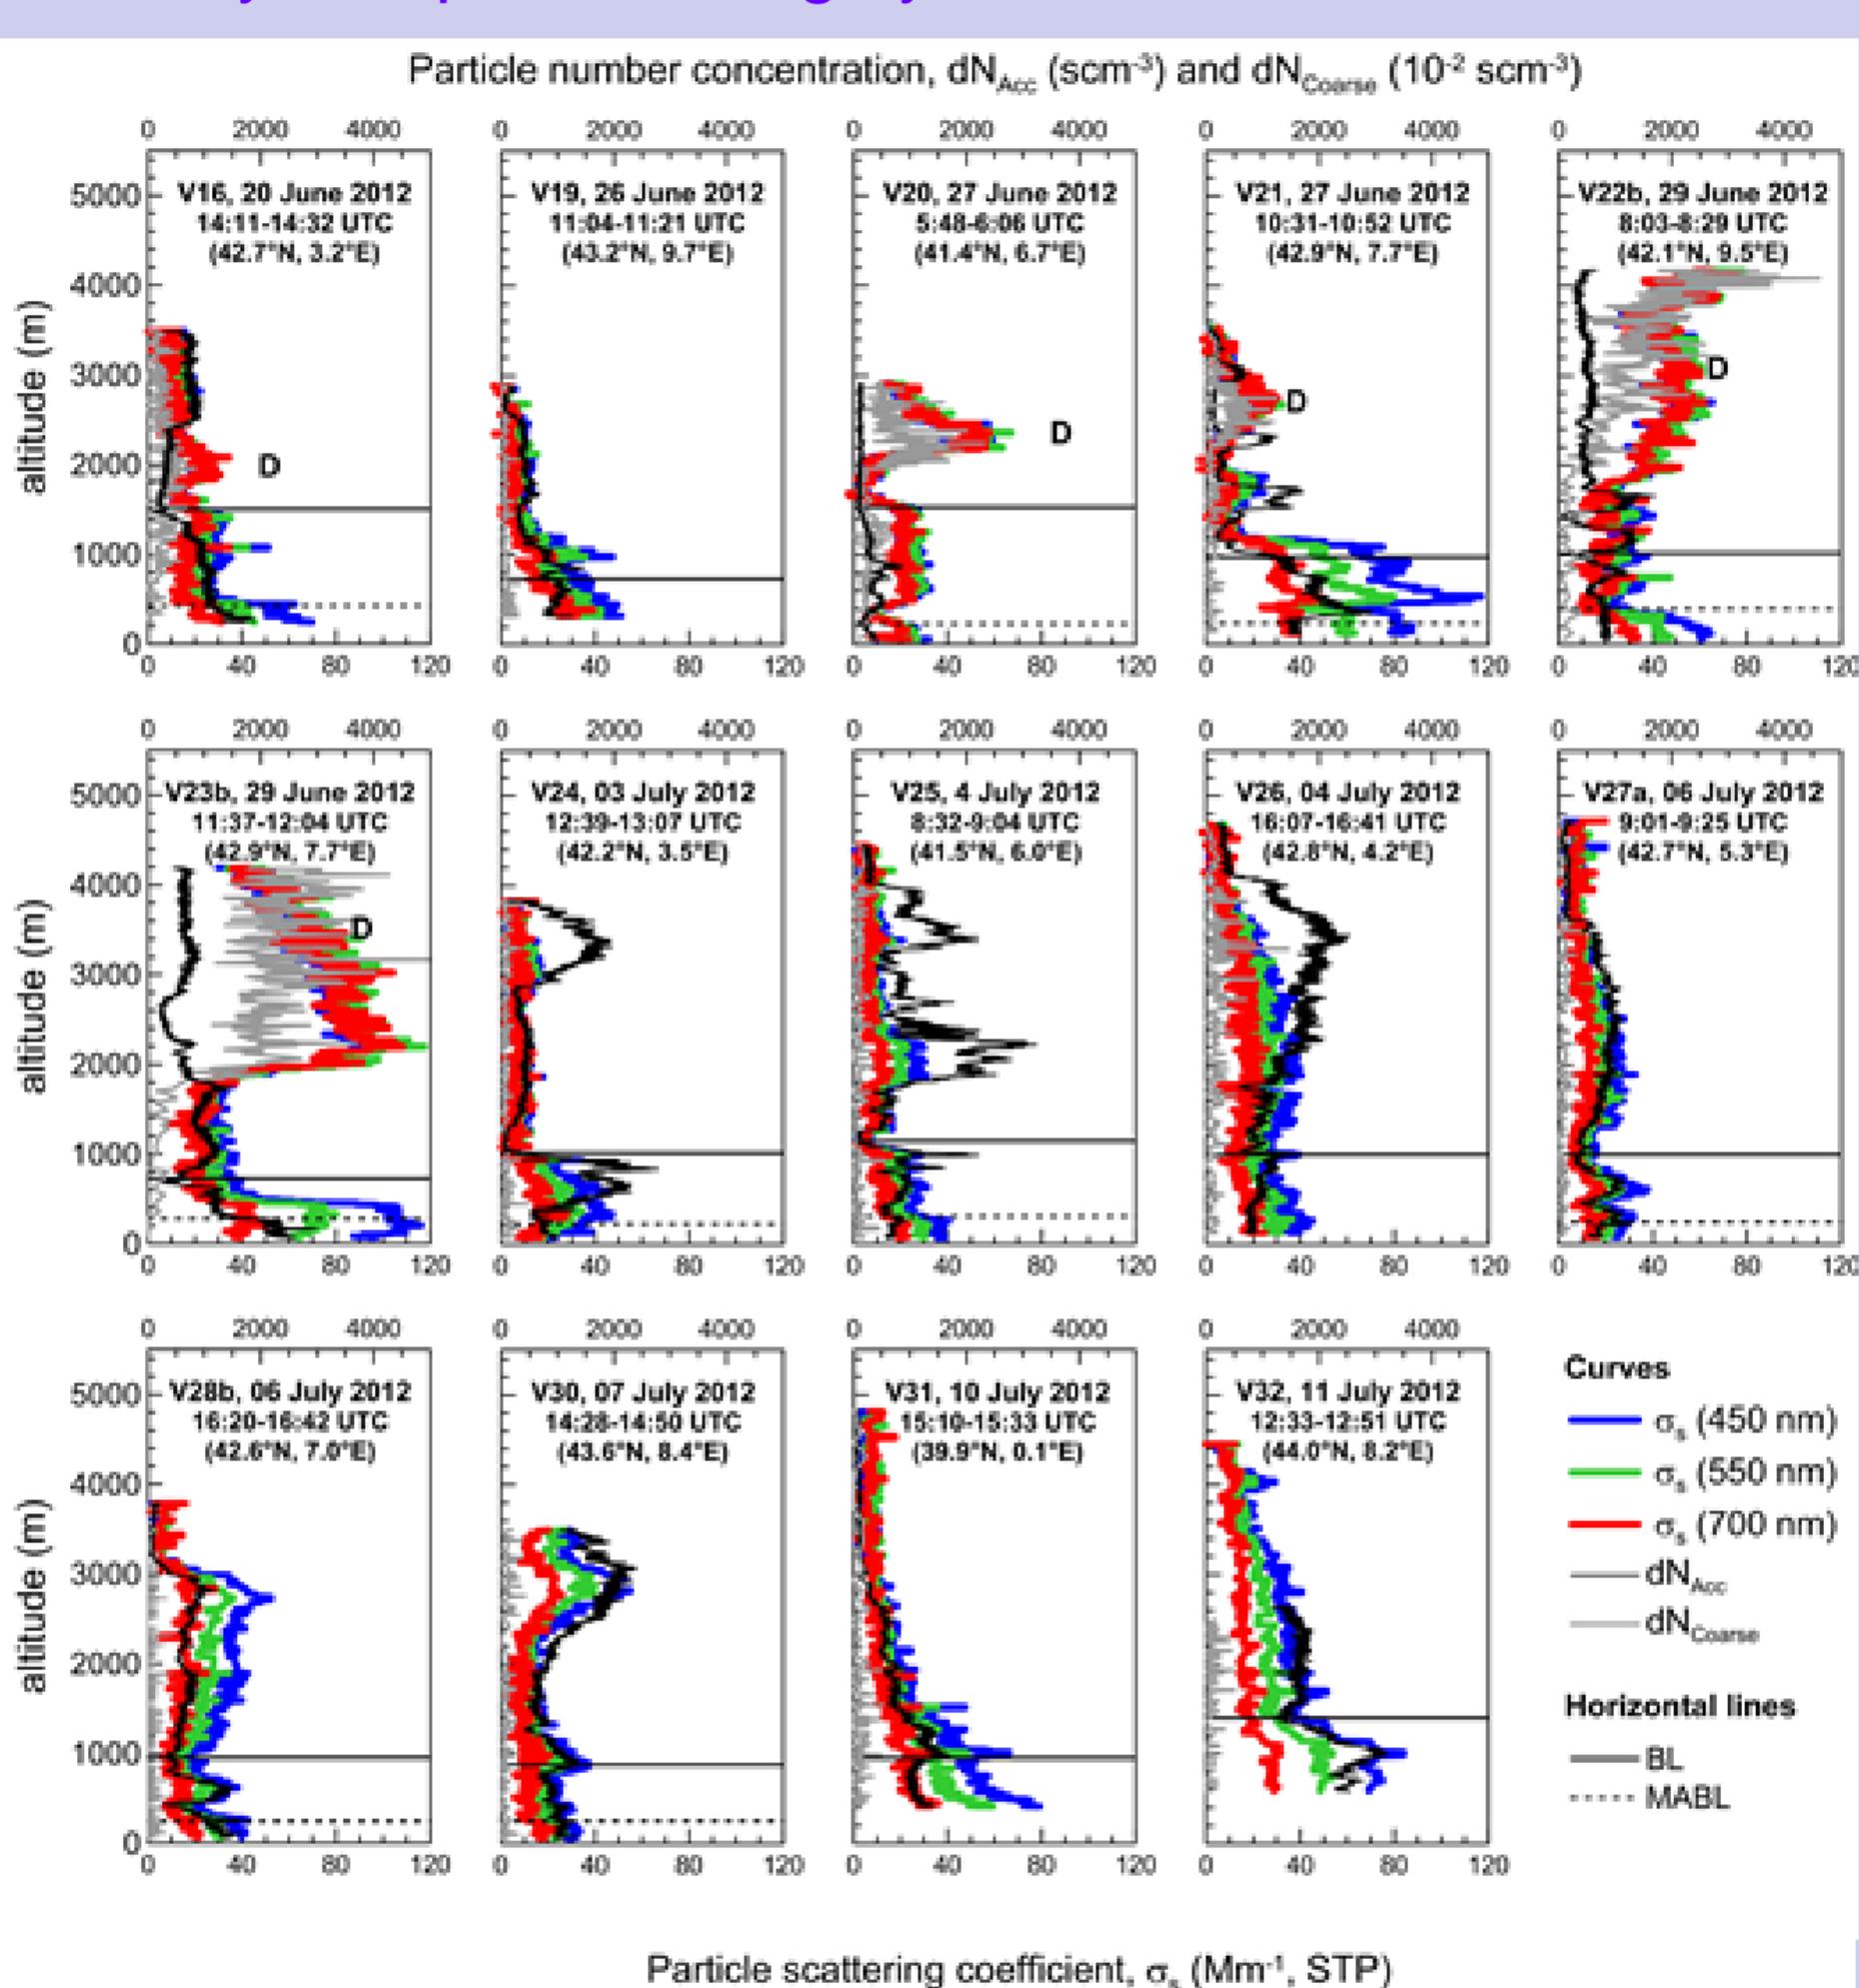

Atmospheric layer	Parameter	TRAQA/SAFMED	Literature over continental Europe
Free troposphere (FT)	dN <sub>Aitken</sub> (scm <sup>-3</sup> )	0-19250	0-9149
	dN <sub>Acc</sub> (scm <sup>-3</sup> )	34-3233	0-500
Boundary layer (BL)	dN <sub>Aitken</sub> (scm <sup>-3</sup> )	4-22471	0-31370
	dN <sub>Acc</sub> (scm <sup>-3</sup> )	90-3215	0-2000

dN<sub>Aitken</sub> (0.004-0.1  $\mu\text{m}$ ) dN<sub>Acc</sub> (0.1-1.0  $\mu\text{m}$ )

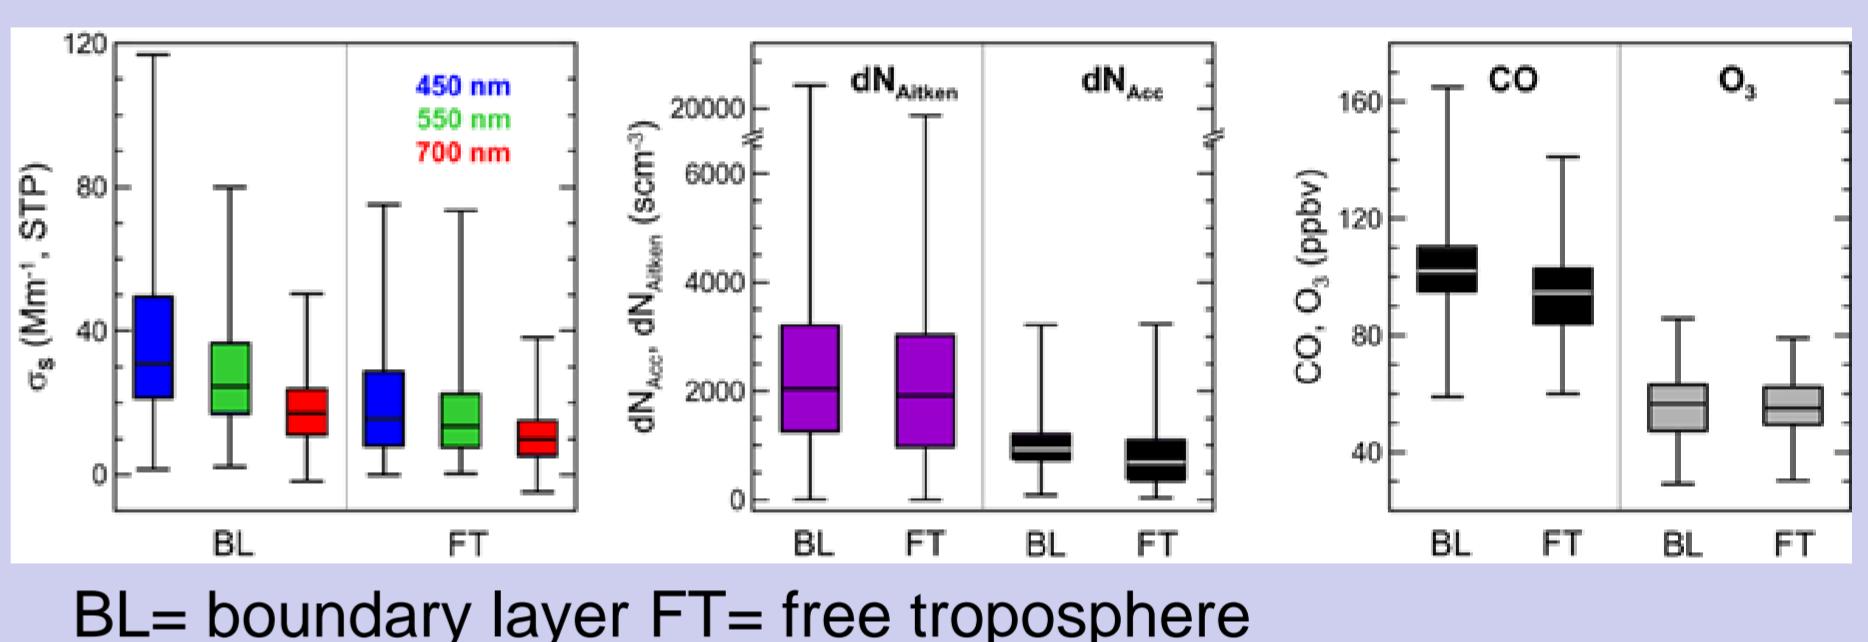

### Extension of pollution plumes from the boundary layer to the free troposphere

- Pollution aerosols reach 3000-4000 m in altitude
- Very complex and highly stratified structure

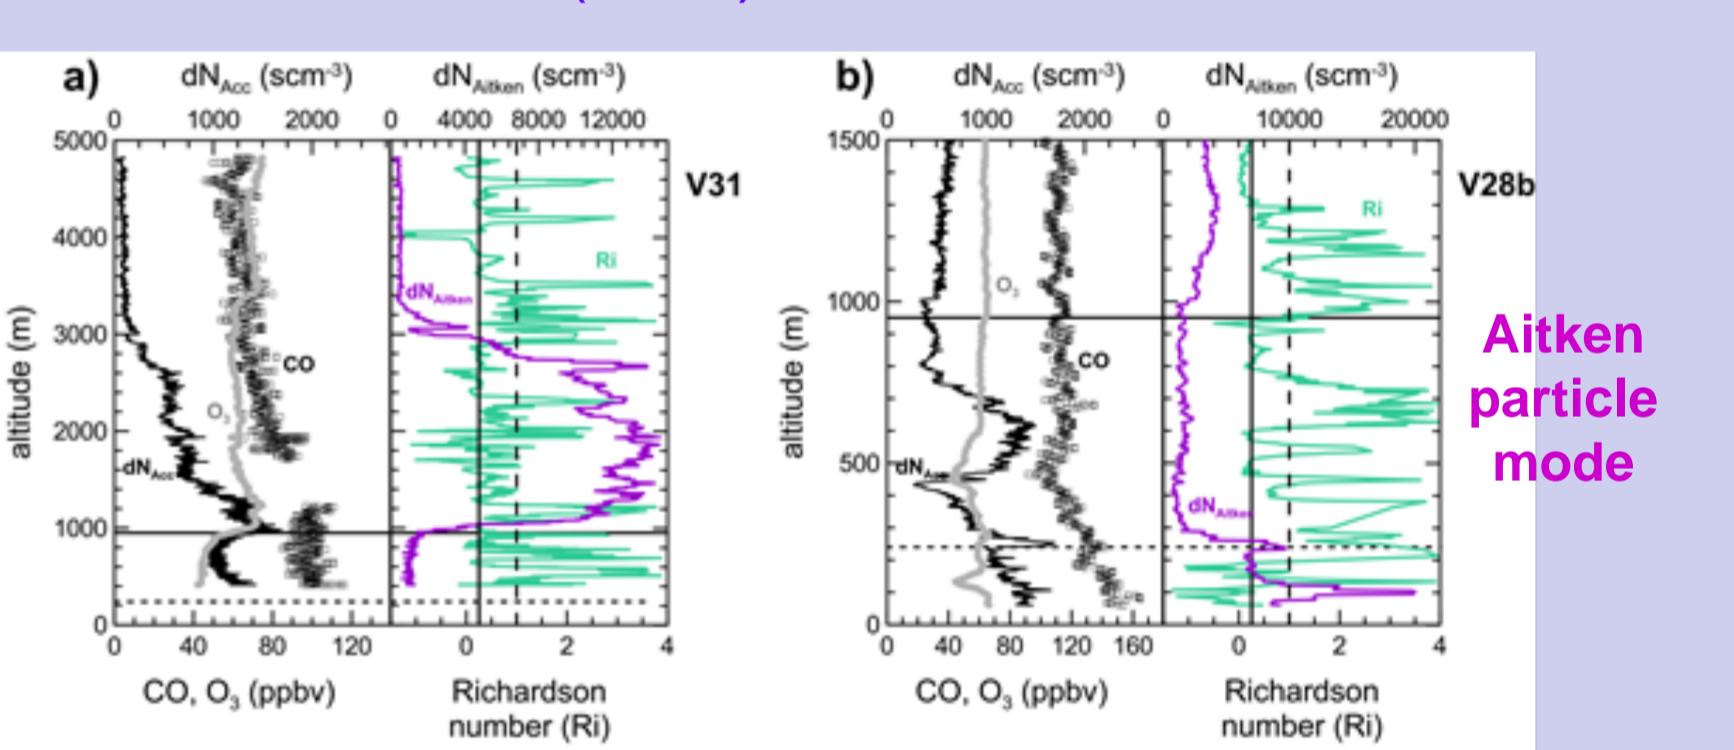

### Variability of pollution plume composition indicating diverse air mass sources, histories, and aging times

- Large variability of measured aerosol scattering coefficient and concentration and O<sub>3</sub> & CO plume content

BL = boundary layer FT = free troposphere

- Contribution of ultrafine particles at all altitudes
- These are due to continental or ship emissions, as well as new particle formation (NPF) events

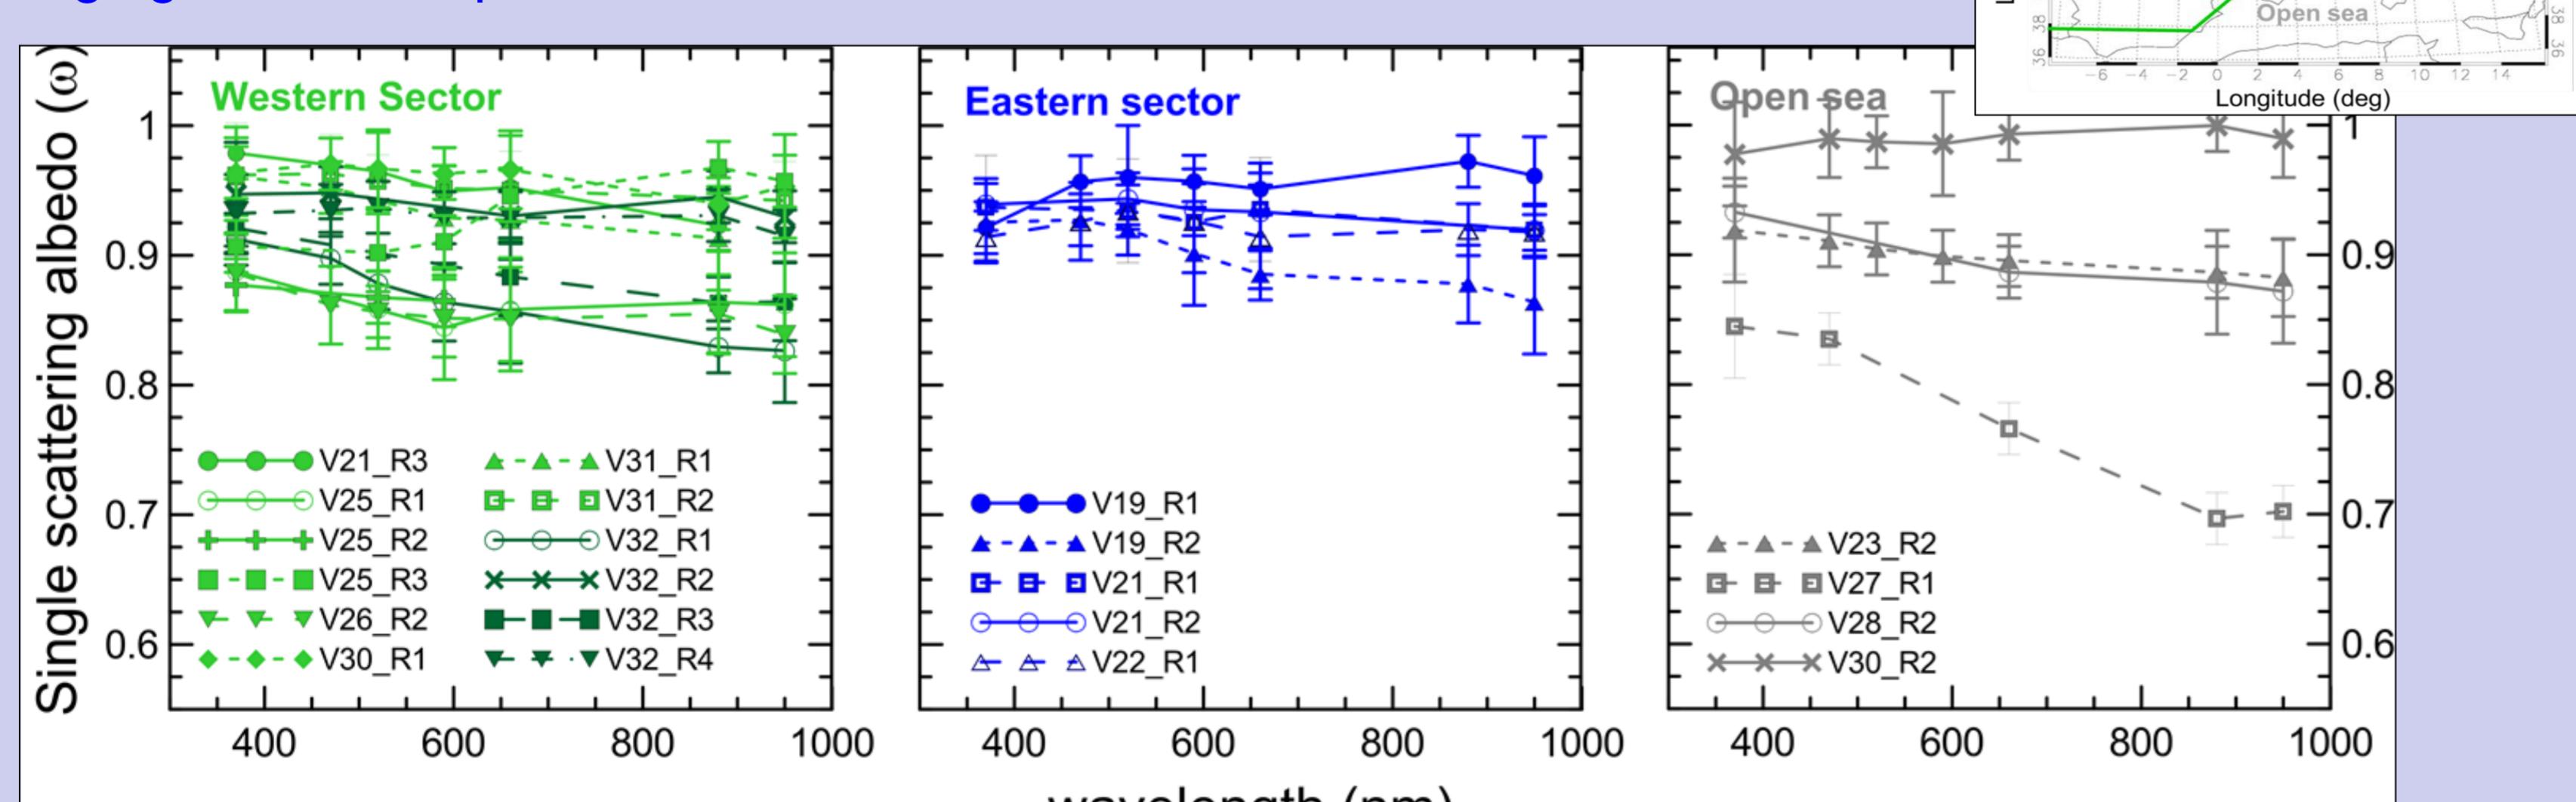

horizontal lines: height of the marine (dotted) and planetary (continuous) boundary layer  
vertical lines: critical Richardson number  $Ri_{crit}=0.25$  (continuous) and  $Ri=1$  (dashed)  
( $Ri < R_i_{crit}$  indicates favorable conditions for the development of turbulence)

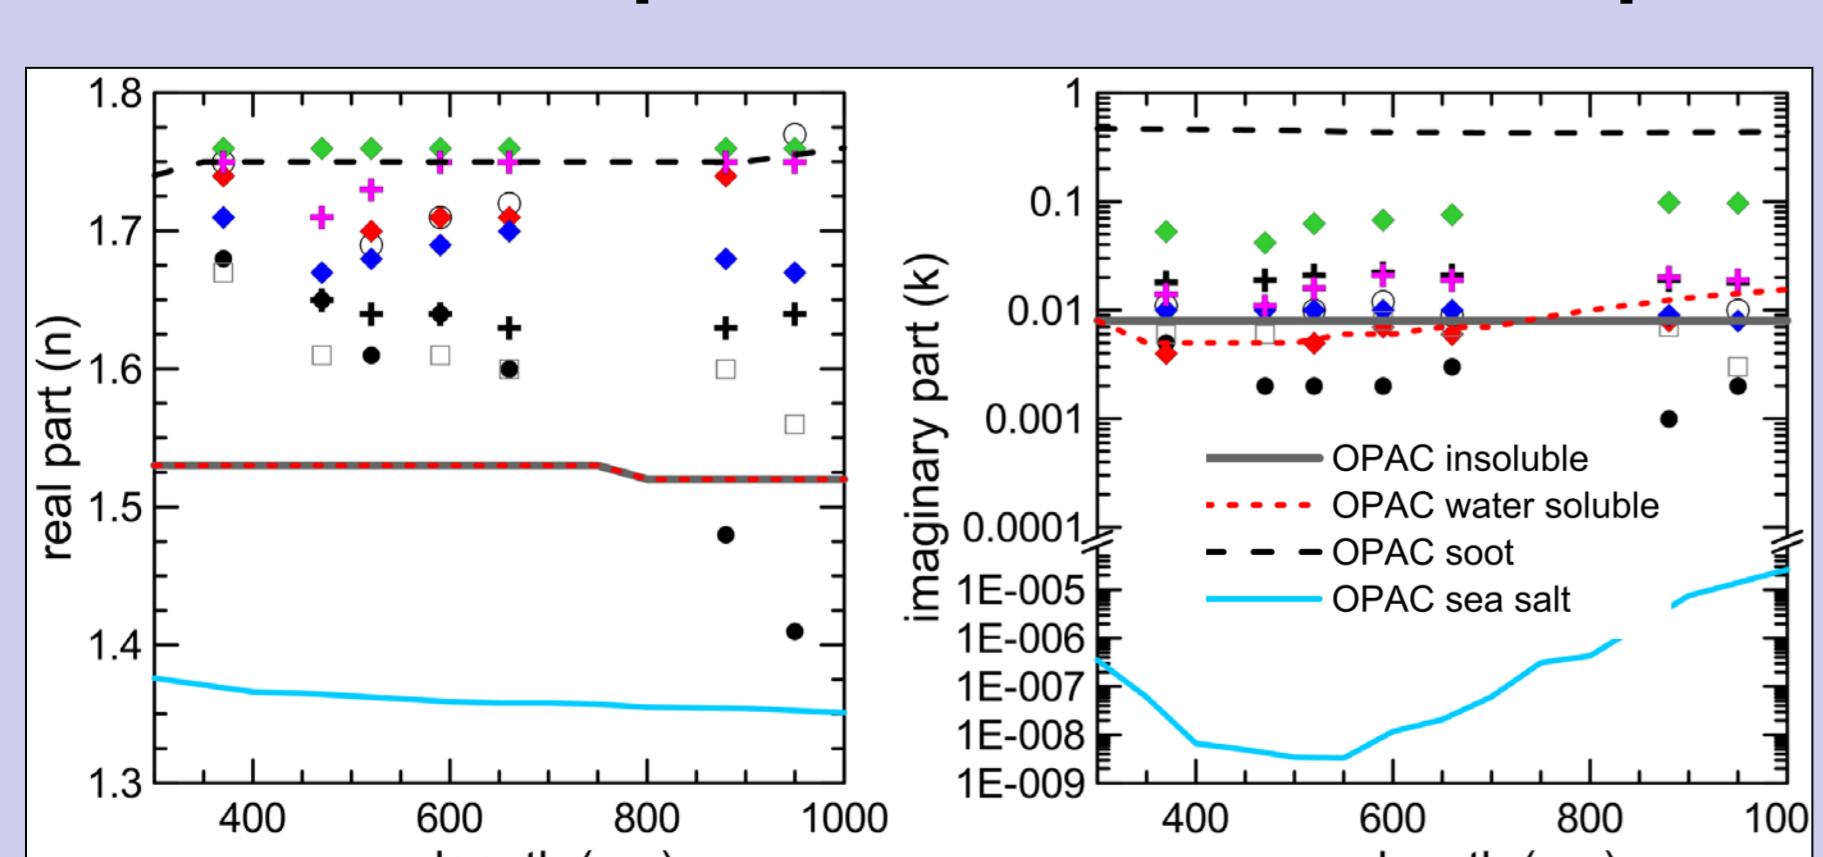

## Optical properties and direct radiative effect of pollution aerosols in the western Mediterranean

### Large variability of the pollution aerosol single scattering albedo (SSA)

- The SSA varies in the range 0.84-0.98 at 370 nm and 0.70-0.99 at 950 nm
- This variability seems to be independent of the source region, altitude and aging time of the plumes

The SSA variability reflects in a large variability for the complex refractive index for pollution aerosols

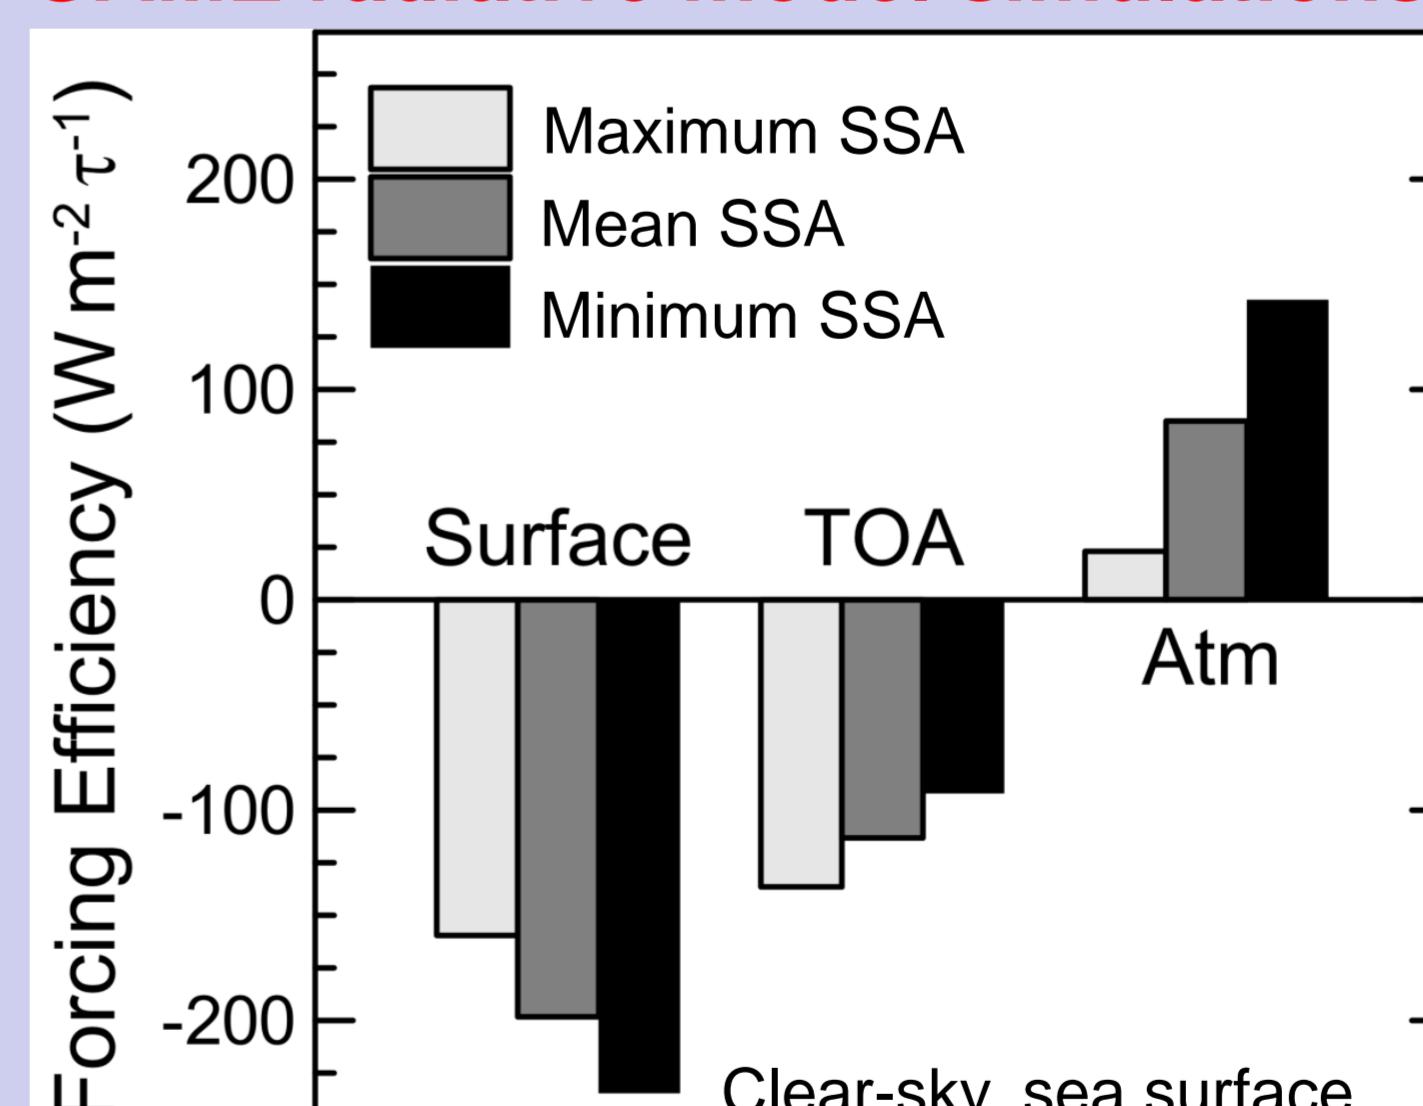

Range of variability of the refractive index for pollution aerosols. Data are compared to the refractive indices for single aerosol constituents (OPAC dataset)

The refractive index is obtained by optical closure by combining optical and size aerosol data.

The pollution aerosol shortwave forcing efficiency strongly varies due to the SSA variability

### GAME radiative model simulations

Spectral range	0.28-3.0 $\mu\text{m}$
Solar zenith angle	60°
Albedo of the sea surface	0.009 (0.448 $\mu\text{m}$ ) – 0.005 (2.13 $\mu\text{m}$ )
Aerosol optical depth	0.20 (0.55 $\mu\text{m}$ )
Aerosol Ångström exponent	1.5
Aerosol asymmetry factor	0.60 (0.33 $\mu\text{m}$ ) – 0.51 (1.5 $\mu\text{m}$ )
Aerosol Single Scattering Albedo (SSA)	
Max	0.98 (330 nm) – 0.99 (1500 nm)
Mean	0.93 (330 nm) – 0.89 (1500 nm)
Min	0.88 (330 nm) – 0.80 (1500 nm)
