Abstract. Rhopalosomatidae are a family of aculeate wasps that are ectoparasitoids of crickets as larvae and are predominantly distributed pantropically. The published fossil record of the family is scarce. Here, we report three new fossil rhopalosomatid wasp specimens from Dominican and Mexican amber. *Rhopalosoma hispaniola* Lohrmann sp. nov. is described and documented from Dominican amber by two separate inclusions – one of each sex. An additional fossil female *Rhopalosoma* is described and documented from Mexican amber but is not named due to the insufficient preservation of the fossil. The new fossils, which are morphologically intermediate between Townes' *isopus* and *poeyi* species groups, do not only represent the first fossil records of an extant genus of this peculiar family but also the first records of the family in Dominican and Mexican amber.

1 Introduction

The Recent New World fauna of Rhopalosomatidae is currently comprised of 35 formally described species assigned to three genera: *Liosphex* Townes, 1977, with 13 species, *Olixon* Cameron, 1887, with 5 species, and *Rhopalosoma* Cresson, 1865, with 17 species (Townes, 1977; Lohrmann and Oehl, 2010; Lohrmann et al., 2012). Their distribution ranges from southeastern Canada and the northeastern USA to northern Argentina and southern Brazil, with the vast ma-

jority occurring in the tropic zone. As far as it is known, female rhopalosomatids hunt for crickets (Orthoptera) that ultimately serve as hosts for their ectoparasitoid larvae (Perkins, 1908; Hood, 1913; Gurney, 1953; Lohrmann et al., 2014; Blaschke et al., unpublished results; see also Fig. 1a–b).

The recent discovery of an ectoparasitoid rhopalosomatid wasp larva attached to its cricket host in mid-Cretaceous Burmese amber revealed a remarkable constancy of the biology of Rhopalosomatidae over the last 100 million years (Lohrmann and Engel, 2017). In some way, this extraordinary fossil hides the fact that we still know little about the origin and evolution of this peculiar family of aculeate wasps. Two of the four fossil taxa previously assigned to the family, *Mesorhopalosoma* Darling (in Darling and Sharkey, 1990) and *Paleorhopalosoma* Nel et al., 2010, have been transferred to the sphecoid wasps (Osten, 2007; Archibald et al., 2018). Additionally, *Propalosoma* Dlussky and Rasnitsyn, 1999, has been transferred to the myrmeciine ants (Archibald et al., 2018). This leaves *Eorhopalosoma* Engel, 2008, which is another Cretaceous Burmese amber fossil, as the sole fossil species in the family so far.

No Rhopalosomatidae have been recorded from Dominican and/or Mexican amber, even though many of the extant aculeate families currently distributed in the neotropics are already reported from either of these contemporary outcrops. For Dominican amber, these include Andrenidae, Apidae, Bethyridae, Chrysididae, Crabronidae, Colletidae, Dryinidae, Formicidae, Halictidae, Megachilidae, Mutilli-

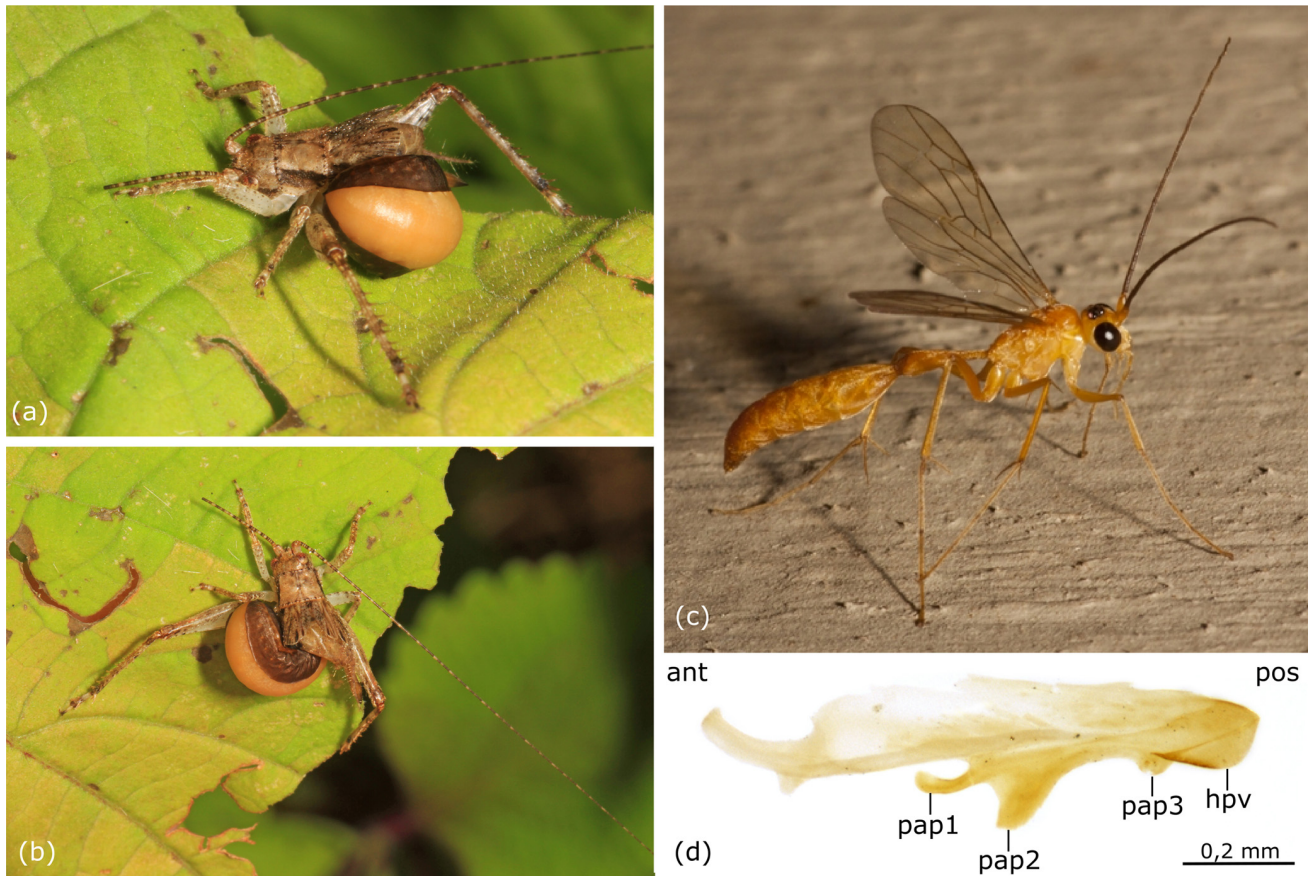

Figure 1. Rhopalosomatidae spp. (a–b) Recent rhopalosomatid larva (last instar, shortly before leaving the host, putatively *Rhopalosoma nearcticum* Brues) parasitizing a hapithine cricket (Grylloidea). dae, Pompilidae, Sclerogibbidae, Scolebythidae, and Vespidae (Penney, 2010; Rodriguez et al., 2016). For Mexican amber, these include Apidae, Bethyidae, Dryinidae, and Formicidae (Solórzano Kraemer, 2010).

Due to their general appearance, members of the rhopalosomatid wasp genus *Rhopalosoma* (see Fig. 1c), as well as the Old World *Paniscomima* Townes, 1977, are often mistaken for nocturnal ichneumonids, e.g., *Ophion* spp. or *Netelia* spp. (McGown, 1998), and one is strongly encouraged to go through collections of unidentified subtropical or tropical nocturnal ichneumonids when searching for material of the genus. This is also true for the fossil record. During our surveys of fossil inclusions, three adult rhopalosomatid wasps have been discovered in Dominican and Mexican amber, and one of the fossils described herein was indeed initially identified and advertised as a “Large Ichneumonid Wasp”.

All three of the new fossils belong to the Recent genus *Rhopalosoma*. The aim of the present study is to describe

and illustrate these fossils, which are not only the first fossil records of the genus but are also the first of the family from Dominican and Mexican amber and from the Miocene as a whole.

2 Materials and methods

2.1 Thermochemolysis–gas chromatography–mass spectrometry

Of the three new rhopalosomatid fossils reported herein, each is preserved in a separate amber piece. Two of these fossils originate from the La Bucara mine in the Dominican Republic, and one comes from a mine in Mexico (Chiapas). Because the Mexican amber piece was obtained from an online auction, without an indication of the exact provenance in Chiapas, we performed a chemical analysis to ascertain its amber vs. copal nature and its affinities with genuine Chiapas amber. Thermochemolysis–gas chromatography–mass

spectrometry (THM-GC-MS) was performed on both the Mexican amber sample and a piece of yellowish Baltic amber as a reference chromatogram. Small portions of amber were crushed manually in an agate mortar. The powder (~ 0.1 mg) was heated with TMAH (tetramethylammonium hydroxide) at 400°C . THM was carried out using a Frontier Lab PY-2020iD pyrolyzer coupled with a Shimadzu GCMS-QP2010 Plus system operating with a split ratio of 100. Separation was achieved using a capillary column SLB-5ms ($60\text{ m} \times 0.25\text{ mm}$ inner diameter – ID, $0.25\ \mu\text{m}$ film thickness) with the carrier gas He with a flow of $1.1\ \text{mL min}^{-1}$. The operating conditions were as follows. The initial temperature was held at 50°C for 2 min and was increased to 310°C at a rate of 4°C min^{-1} for 34 min. Individual compounds were identified based on comparison of (i) MS data with the NIST 2014 library and literature (Anderson, 1994, 1995) and (ii) retention time with the Baltic amber. The molecules were referenced according to Anderson (1995).

The relative distribution of identified compounds was determined by measuring the area of a specific fragment, denoted as m/z integration in Appendix A. The peak area of the selected m/z for each compound was integrated and corrected by a mass spectra factor (Appendix A) calculated as the reciprocal of the proportion of the fragment used for the integration and the entire fragmentogram. The molecular ratios were calculated using those corrected areas that allow an approximation of areas on the total ion chromatogram, while preventing from the simultaneous analysis of co-eluting compounds.

2.2 Age of the amber

There has been a wide range of proposed ages for Dominican amber, from 45 ± 9 to 15 Ma (Lambert et al., 1985; Schlee, 1990; Landis and Snee, 1991; Grimaldi, 1995). However, most recent studies reviewing its geological dating indicate a late Early to early Middle Miocene age (about 15–20 Ma; Iturralde-Vinent and MacPhee, 1996; Iturralde-Vinent, 2001; and Penney, 2010 for a review). Mexican amber is of similar age (15–20 Ma; Solórzano Kraemer, 2007, 2010, but see Serrano-Sánchez et al., 2015, for a slightly older Miocene dating), which is supported by the similarities of the organismal inclusions of these two amber deposits. Indeed, many insect and arachnid genera are found in both Dominican and Mexican amber (Solórzano Kraemer, 2010). Yet, the authors are not aware of a single species in common described or recorded in both ambers.

2.3 Preparation and study of fossils

All three amber pieces were manually polished using a Buehler MetaServ 3000 polisher and Buehler CarbiMet silicon carbide papers to obtain flat surfaces for optimal observation and imaging of the insect inclusions.

The inclusions were studied with a Leica MZ12 and a Zeiss SteREO Discovery.V20 stereomicroscope. Measurements were taken with an ocular micrometer. Extended-focus images were taken with a Leica DFC 490 digital camera with a Leica Z16 Apo A system and a Canon 5D Mark II digital camera attached to the Leica MZ APO stereomicroscope or with the BK PLUS Lab system (Dun Inc.) with a Canon MPE 65 mm lens mounted on a Canon 6D camera. Pictures were aligned and stacked using the software package Auto-Montage Essentials by Syncrosopy (Version 5.03.0061 ES), Helicon Focus software (Helicon Soft Ltd., version 6.7.2), or Zerene Stacker under the PMax value.

The general morphological terminology is adopted from Huber and Sharkey (1993), with additions from Mason (1986, 1990), and the following morphological abbreviations and modifications are used in the text. Cu^2 is the section of fore wing cubitus separating the 2Cu and 2M (not closed) cells (Fig. 4f). IOD is the interocellar distance, or the shortest distance between the lateral ocelli. LOD is the maximum diameter of a lateral ocellus. MOD is the maximum diameter of the median ocellus. M^1 is the section of fore wing media separating the R and 1M cells (Fig. 4f). M^2 is the section of fore wing media separating the 1M and 1Rs cells (Fig. 4e). OOD is the ocellular distance, or the shortest distance between the lateral ocellus and eye. Rs^1 is the section of fore wing radial sector separating the 1R1 and 1Rs cells (Fig. 4e). Rs^* is the section of hind wing radial sector separating the R and R1 cells (Fig. 5e). TL is the temple length, or the shortest distance between the posterior eye margin and occipital carina.

All three specimens are deposited in the amber collection of the Museum für Naturkunde in Berlin, Germany (inventory numbers: MB.I 5915, MB.I 6046, and MB.I 6549).

2.4 Reference material studied

During the course of this research, the holotypes of *Rhopalosoma alvarengai* Townes, 1977, *R. angulare* Townes, 1977, *R. breelandi* Townes, 1977, *R. impar* Townes, 1977, *R. isopus* Townes, 1977, *R. minus* Townes, 1977, *R. obliquum* Townes, 1977, and *R. scaposum* Townes, 1977, all deposited in the Entomology Collection of Utah State University (EMUS), previously known as the American Entomological Institute (AEI), were studied. Additionally, non-type material of the EMUS, including *R. bahianum* Schulz, 1906, *R. breelandi*, *R. guianense* Schulz, 1906, *R. haitiense* Townes, 1977, *R. impar*, *R. isopus*, *R. minus*, *R. nearcticum* Brues, 1943, *R. poeyi* Cresson, 1865, and *R. simile* Brues, 1943, was also studied.

2.5 Nomenclatural acts

This published work and the nomenclatural acts it contains have been registered in ZooBank (<http://www.zoobank.org/>, last access: 1 October 2018), with the following LSID

(reference): urn:lsid:zoobank.org:pub:1BA7DC1A-E890-465C-BF6D-F0A95C131B48. The electronic edition of this work has been archived and is available from the following digital repositories: Deutsche Nationalbibliothek, US Library of Congress, Portico, and CLOCKSS.

3 Results

3.1 Chemical analysis

The THM-GC-MS analysis of the Mexican resin sample (Fig. 2; see also Appendix B) revealed characteristic bicyclic products derived from polylabdanoid structures including carboxylic acids (XIa–XIVa), analyzed as their methyl ester; alcohols (XIIIb–XIVb) partially methylated (XIIIc–XIVc); and hydrocarbons (XIc, XIIIc and XIVc). Moreover the THM of this sample also produced 1-methylbicyclic hydrocarbons (A–K) that are believed to come from A-ring defunctionalization (Anderson, 1995).

The shift in the retention times of methylic ether XIIIc and XIVc between the Baltic amber and the Mexican resin (Fig. 3) indicated an enantio configuration for the latter. Consequently, it falls into the class Ic as defined by Anderson et al. (1992). The distribution of bicyclic products derived from the polylabdanoid macromolecular structure of the Mexican sample was dominated by 1-dimethylbicyclic and 1-methylbicyclic hydrocarbons (50 % and 28 %, respectively), while bicyclic acids and alcohols represented only 6 % and 17 % of those compounds, respectively (Table 1). This predominance of 1-dimethylbicyclic hydrocarbons was already observed in Sicilian amber (van der Werf et al., 2016).

The composition was compared to those of known class Ic ambers from the Eocene of Oise (France; Nohra et al., 2015) and the Miocene of the neotropics (the Dominican Republic and Mexico, from the collection of Vincent Perrichot, Univ. Rennes, unpublished results). The relative proportions of carboxylic acids, alcohols, and hydrocarbons among bicyclic products derived from polylabdanoid structures were similar in the Mexican sample and the two neotropical ambers, while the Oise amber was richer in carboxylic acids (Table 1). The proportion of 1-methylbicyclic hydrocarbons was proposed as a maturity proxy, since they are especially observed in samples of moderate thermal maturity (Anderson, 1995). The present Mexican sample (28 %) falls between Oise (19 %) and Dominican (22 %) ambers on one side and Mexican amber (41 %) on the other side, thus attesting to its amber rather than copal nature as well as its affinity with neotropical ambers.

With the exception of the earliest record of a class Ic amber from the Carboniferous (Bray and Anderson, 2009), all other known Ic ambers are Cenozoic and are derived from angiosperms of the legume family Fabaceae (Lambert et al., 2008; Nohra et al., 2015; van der Werf et al., 2016), particularly the genus *Hymenaea* Linnaeus that produced neotropical Miocene ambers from the Dominican Republic and Mexico (Anderson et al., 1992; Anderson, 1995).

3.2 Systematic paleontology

Order Hymenoptera Linnaeus, 1758

Family Rhopalosomatidae Ashmead, 1896

Genus *Rhopalosoma* Cresson, 1865

LSID (genus): urn:lsid:zoobank.org:act:F41B7AB7-0F40-40E6-AEC3-0B01AF718AF1

Rhopalosoma Cresson, 1865:58. Type species: *Rhopalosoma poeyi* Cresson, 1865, by monotypy.

Sibyllina Westwood, 1868:329. Type species: *Sibyllina aenigmatica* Westwood, 1868, by monotypy. Synonymy by Westwood, 1874: 130.

Diagnosis

Among extant and fossil rhopalosomatids, species of *Rhopalosoma* are characterized by the following character combination. The wings are fully developed (brachypterous in *Olixon*); the occipital carina is present (absent in *Liosphex*); the apical section of the fore wing cubitus (Cu² in Fig. 4) is at least slightly sinuate (arched, but indented at the level of junction with CuA in *Paniscomima*, and almost straight in *Eorhopalosoma*); female pretarsal claws have a preapical tooth (as in Figs. 4b, 6c); female tarsomeres II–IV have apicolateral tarsal fenestrae (Fig. 6b); and the second preapical process of the male penis valve is narrow to broad, distad from the head of the penis valve, and is not overlapped at its apex by the third preapical process (Fig. 1d; broadly triangular, near head of penis valve, and overlapped in *Paniscomima*).

(Males and females of the family can be differentiated by the number of flagellomeres – males have 11, and females have 10, by the number of visible metasomal tergites – males have 7, and females have 6, and by the form of tarsomeres II–IV – cylindrical for males and flattened for females. For a more detailed morphological description of the genus and all extant species, including a species-level identification key, the family revision of Townes (1977), should be consulted.)

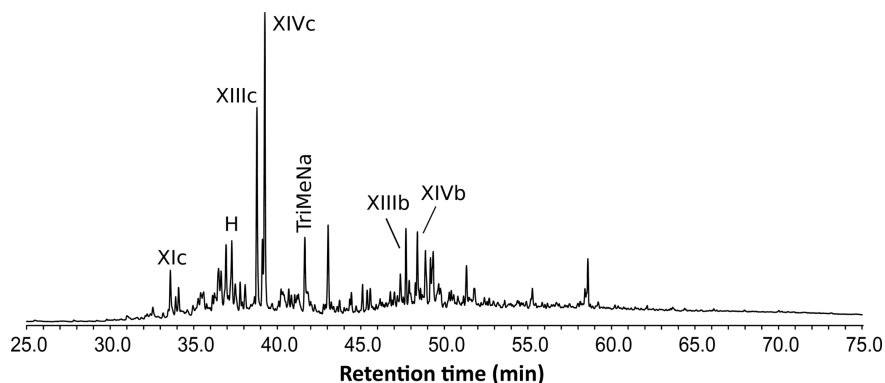

Figure 2. Chromatogram from the THM-GC-MS analysis of the Mexican sample. Numbered peaks refer to identified compounds in Appendix A. TriMeNa is trimethylnaphthalene.

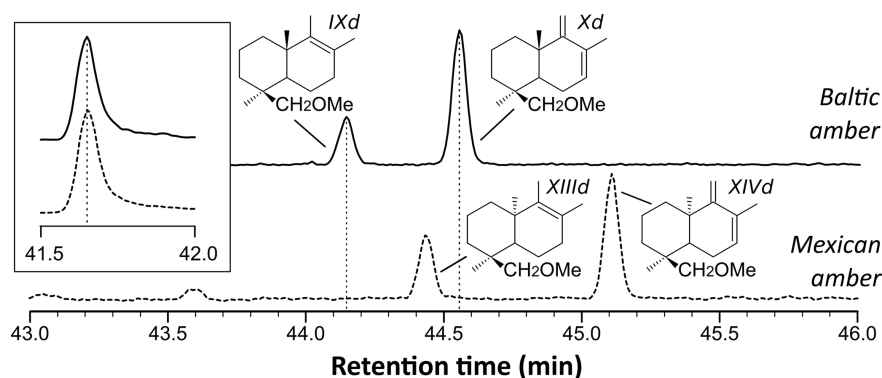

Figure 3. Reconstructed chromatogram ($m/z = 234 + 236$) of Baltic amber (solid line) and Mexican sample (dashed line). The shift in the retention times of compounds XIIIId and XIVd (Mexican amber) compared to IXd and Xd (Baltic amber) is due to the difference of configuration between the *enanti* and *regular* forms, which classifies the Mexican sample as a class Ic resinite. The box depicts the similar retention time for trimethylnaphthalene ($m/z = 155$).

Distribution

Distribution is predominantly in the tropics and subtropics of the Americas (eastern United States to southern Brazil and northern Argentina), including some of the Caribbean countries (Bahamas, Cayman Island, Cuba, and Haiti; Townes, 1977).

Biology

As it concerns the extant fauna, *Rhopalosoma nearcticum* Brues, 1943, has been associated with species of trigonidine and hapithine genera (Insecta: Orthoptera), i.e., *Anaxipha* Saussure, 1874, *Hapithus* Uhler, 1864, and *Orocharis* Uhler, 1864 (Hood, 1913 – misidentified as *R. poeyi* Cresson, 1865; Gurney, 1953; Townes, 1977; Blaschke et al., unpublished results; see also Fig. 1a–b). For the remaining 16 extant species in the genus, however, no data have been published to date on their host–parasite relationships.

Rhopalosoma hispaniola Lohrmann sp. nov.

LSID (species): urn:lsid:zoobank.org:act:6BEECB2C-0403-4F5C-93DF-04590CF406DA

LSID (author): urn:lsid:zoobank.org:author:05A758C9-462A-422C-B8D6-DD9530E2BD05

(Figs. 4, 5)

Diagnosis

Within *Rhopalosoma*, females of *R. hispaniola* are unique in showing the following character combination: hind wing Rs^* is straight and recurrent, and the apical 0.65 of fifth tarsomeres is tapered. Males of *R. hispaniola* resemble *R. minus* Townes, 1977, in having a straight, recurrent hind wing Rs^* but can be differentiated by the position of the fore wing cu-a, which is distad of M^1 by about $1.0 \times$ its length (about $2.0 \times$ in *R. minus*).

Table 1. Relative proportions of characteristic bicyclic products derived from polylabdanoid macromolecular structures of the present Mexican sample compared with three classes of three class-Ic ambers. Amber from Dominican Republic and from Mexico are from the personal collection of Vincent Perrichot (VP coll.), and their chemical fingerprints have not yet been published. In bold: the Mexican amber piece containing the rhopalosomatid wasp studied here.

	Dominican Republic (VP coll.)	Oise, France (Nohra et al., 2015)	Mexico (VP coll.)	Mexico (this study)
Bicyclic acids ^a	15	59	4	6
Bicyclic alcohols ^b	17	14	2	17
Bicyclic hydrocarbons	47	7	53	50
1-Methylbicyclic hydrocarbons	22	19	41	28

^a Analyzed as methyl ester. ^b Sum of alcohols and methyl ethers.

Currently, the genus is represented in the Caribbean only by *Rhopalosoma poeyi* Cresson, 1865, and *R. haitiense* Townes, 1977 (Townes, 1977). However, neither of these species has a similar hind wing Rs^* .

Material

Holotype: female, MB.I 5915, in Miocene amber from the Dominican Republic; the specimen is deposited in the amber collection of the Museum für Naturkunde Berlin. The specimen is almost completely preserved without any significant distortions. However, large parts of the legs are missing. The following syninclusions have been observed: one Collembola and one Mymaridae.

Paratype: male, MB.I 6046, in Miocene amber from the La Bucara mine in the Dominican Republic; the specimen is deposited in the amber collection of the Museum für Naturkunde Berlin. The specimen is completely preserved without any significant distortions. In order to access crucial characters of the fossil the amber piece has been cut into two fragments. The following syninclusions have been observed: two Hymenoptera (Mymaridae), four Diptera, one Isoptera, one large Isoptera wing, one unidentified Insecta, and one Araneae.

Description

Female (Fig. 4). *Measurements.* Total body length (head, without antenna, plus mesosoma plus metasoma) in lateral view 12.0 mm. Maximum head width in dorsal view 2.0 mm. Flagellar length (measured on left antenna with the last segment added from the right antenna) 11.4 mm (including pedicel and scapus 12.1 mm). Mesosomal length in lateral view 3.2 mm. Fore wing length 8.9 mm. Hind wing length 6.5 mm. Metasomal length in lateral view 7.8 mm.

Head. (Base of right flagellum and last flagellomere of left flagellum not preserved.) FI–FV each with a pair of apical bristles. FI shorter than FII, which is about as long as flagellomeres III–V. FVI–FX becoming sequentially shorter from base to apex. Inner margin of compound eye emarginate. Depth of eye notch about the same size as the width of toru-

lus. FI 5.0 ×, FII 8.2 ×, and FVII 9.5 × as long as wide. TL 0.6 ×, OOD 0.25 ×, and MOD 1.0 × LOD.

Mesosoma. Scutellum about half as long as mesoscutum and approximately 3 times as long as metanotum. Mesosternal lobes present, separated from mesosternum by slight constriction.

Fore wing. With eight enclosed cells: C, R, 1Cu, 1R1, 2R1, 1Rs, 1M, and 2Cu. Costal cell very narrow, apically slightly wider, over complete distance narrower than bordering veins. Cell 1Rs about 1.05 × as long as cell 1R1. Vein 1cu-a slightly bowed, distad of M^1 by about 1.0 × its length. Distance between 1cu-a and M^1 about half the distance between 1cu-a and m-cu. Vein Rs^1 straight, about 0.8 × length of M^2 . Pigmented traces of 2m-cu present. Anal cell without longitudinal spurious vein at its center (present in some Recent Asian *Paniscomima*). Pterostigma narrow.

Hind wing. Rs^* straight, recurrent, its anterior section meeting Sc + R at an angle of about 55°. M diverging far beyond cu-a. With two clusters of hamuli. Basal hamuli straight. With 13 distal hamuli, all of same size and curved-and/or hook-like.

Legs. (The following parts of the legs are not preserved: tarsomeres III and following of right fore leg, tarsomere II and pretarsus of left fore leg, distal two-thirds of tarsomere I and tarsomere II of right mid leg, tarsomeres II–IV of left mid leg, distal half of tarsomere I and following of both hind legs.) Fore leg with one tibial spur. Mid leg and hind leg each with two tibial spurs, inner spur of hind tibia at base with dorsal tuft of bristles (calcar). Tarsomeres II–IV with apicolateral fenestrae. Pretarsal claws toothed medially (Fig. 4c). Arolia large.

Metasoma. Segment I about as long as mesosoma. Sting upcurved (Fig. 4a).

Pilosity. Body and wing membranes covered with regular distributed fine, short setae.

Male (Fig. 5). *Measurements.* Total body length (head, without antenna, plus mesosoma plus metasoma) about 7.3 mm. Maximum head width in oblique ventral view about 1.0 mm. Flagellar length (measured on left antenna in ventral view) 5.7 mm (including pedicel and scapus: 6.2 mm).

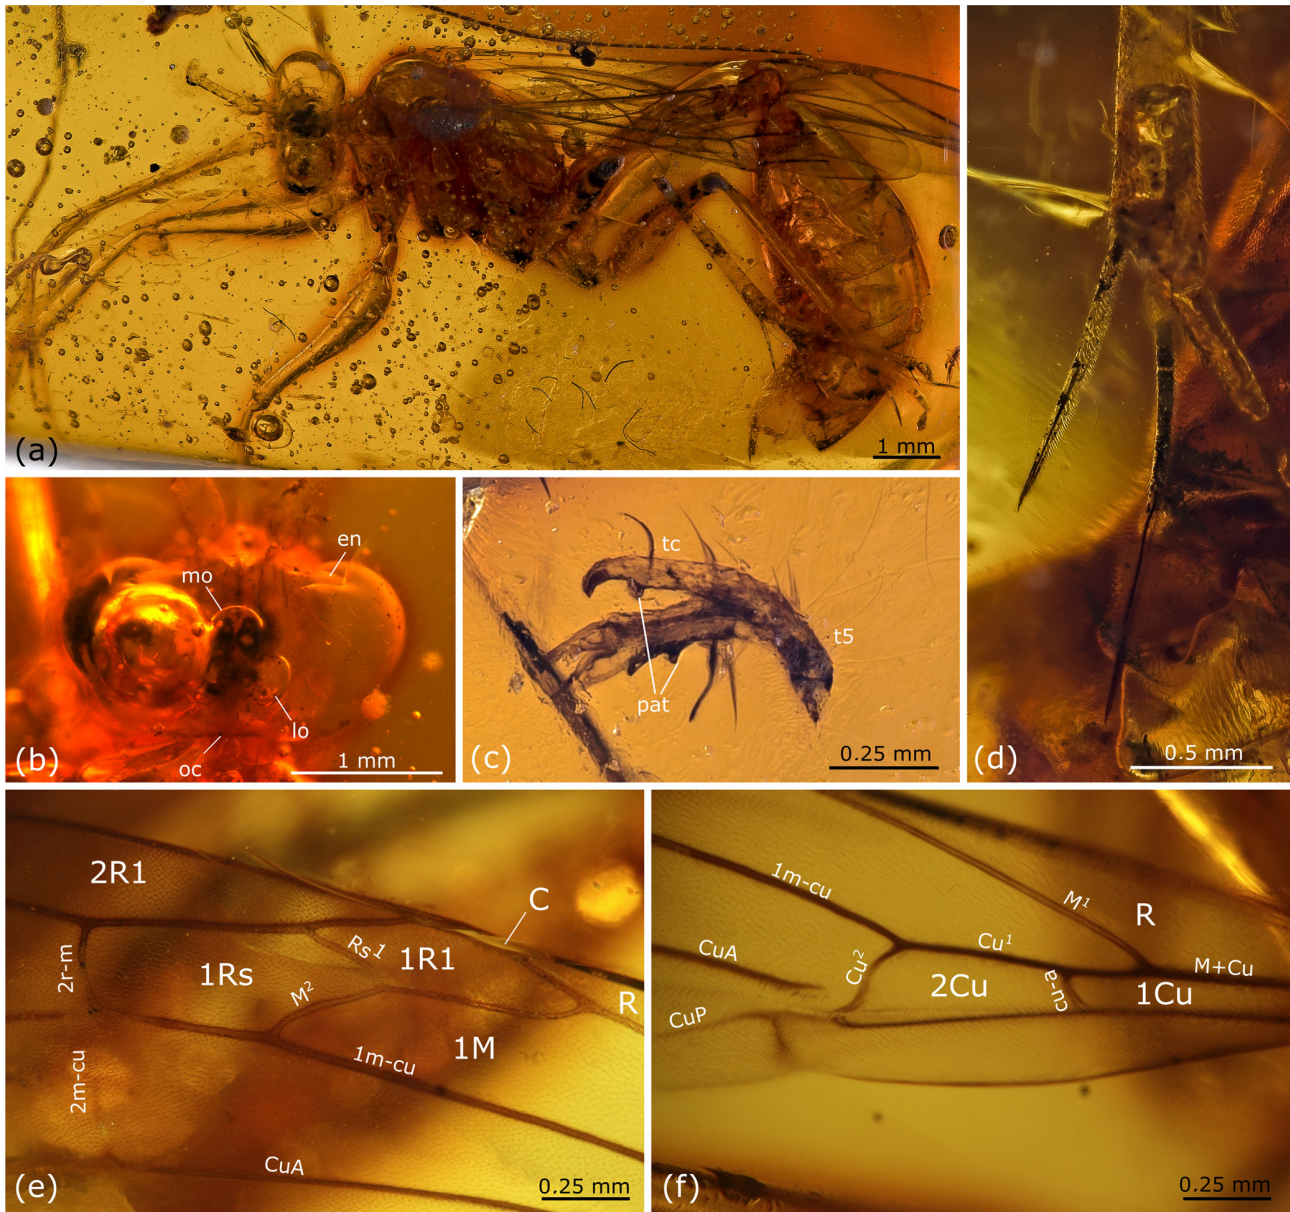

Figure 4. *Rhopalosoma hispaniola* sp. nov.: female, holotype, MB.I 5915, Miocene Dominican amber. (a) Overview. (b) Detail of the head in dorsal view. (c) Detail of the tarsal claws. (d) Distal section of mid tibia with tibial spurs. (e–f) Details of the right fore wing. Abbreviations used in (b) and (c): en – eye notch, lo – lateral ocellus, mo – median ocellus, oc – occipital carina, tc – tarsal claw, t5 – tarsomere 5, and pat – preapical tooth.

Mesosomal length in lateral view is about 2.3 mm. Fore wing length about 5.6 mm. Hind wing length about 3.8 mm. Metasomal length about 4.3 mm.

Head, mesosoma, and metasoma as in female except the following. Fore wing cell 1Rs about $0.85 \times$ as long as cell 1R1. Vein Rs1 about $1.25 \times$ length of M^2 . Distance between 1cu-a and M^1 about the same length as the distance between 1cu-a and m-cu. Hind wing Rs* meeting Sc + R at an angle of about 50° . With eight distal hamuli. Plantar lobe present on tarsomeres I–IV. Pretarsal claws bifid. Metasomal

segment I only two-thirds the length of mesosoma. Cuspis with ~ 12 peg-like bristles on apical section and ~ 6 apical setae. Digitus with ~ 33 peg-like bristles on apical section. Paramere spine-like, upcurved. Cercus paddle shaped and with apical setae.

Note

The intraspecific variation between the non-sex-specific characters (e.g., ratio of the length of fore wing veins Rs¹ and

Figure 5. *Rhopalosoma hispaniola* sp. nov.: male, paratype, MBI 6046, Miocene Dominican amber. (a) Overview. (b) Posterior metasoma with genitalia. (c) Details of right fore wing. (d–e) Details of right fore and hind wing with labeling of fore wing cells and venation (d) and labeling of hind wing venation (e). Abbreviations used in (b): ce – cercus, cu – cuspis, di – digitus, pa – paramere, pv – penis valve, tg6 – tergite 6, and tg7 – tergite 7.

M^2 , ratio of the length of fore wing cells 1Rs and 1R1) seems to be slightly higher than in the Recent species of *Rhopalosoma*. However, we chose a conservative approach by assigning both specimens to the same species rather than describing two species based on only a single specimen of each sex.

Etymology

The specific epithet refers to the island of Hispaniola in the Caribbean where the fossils were found. It is a noun in apposition.

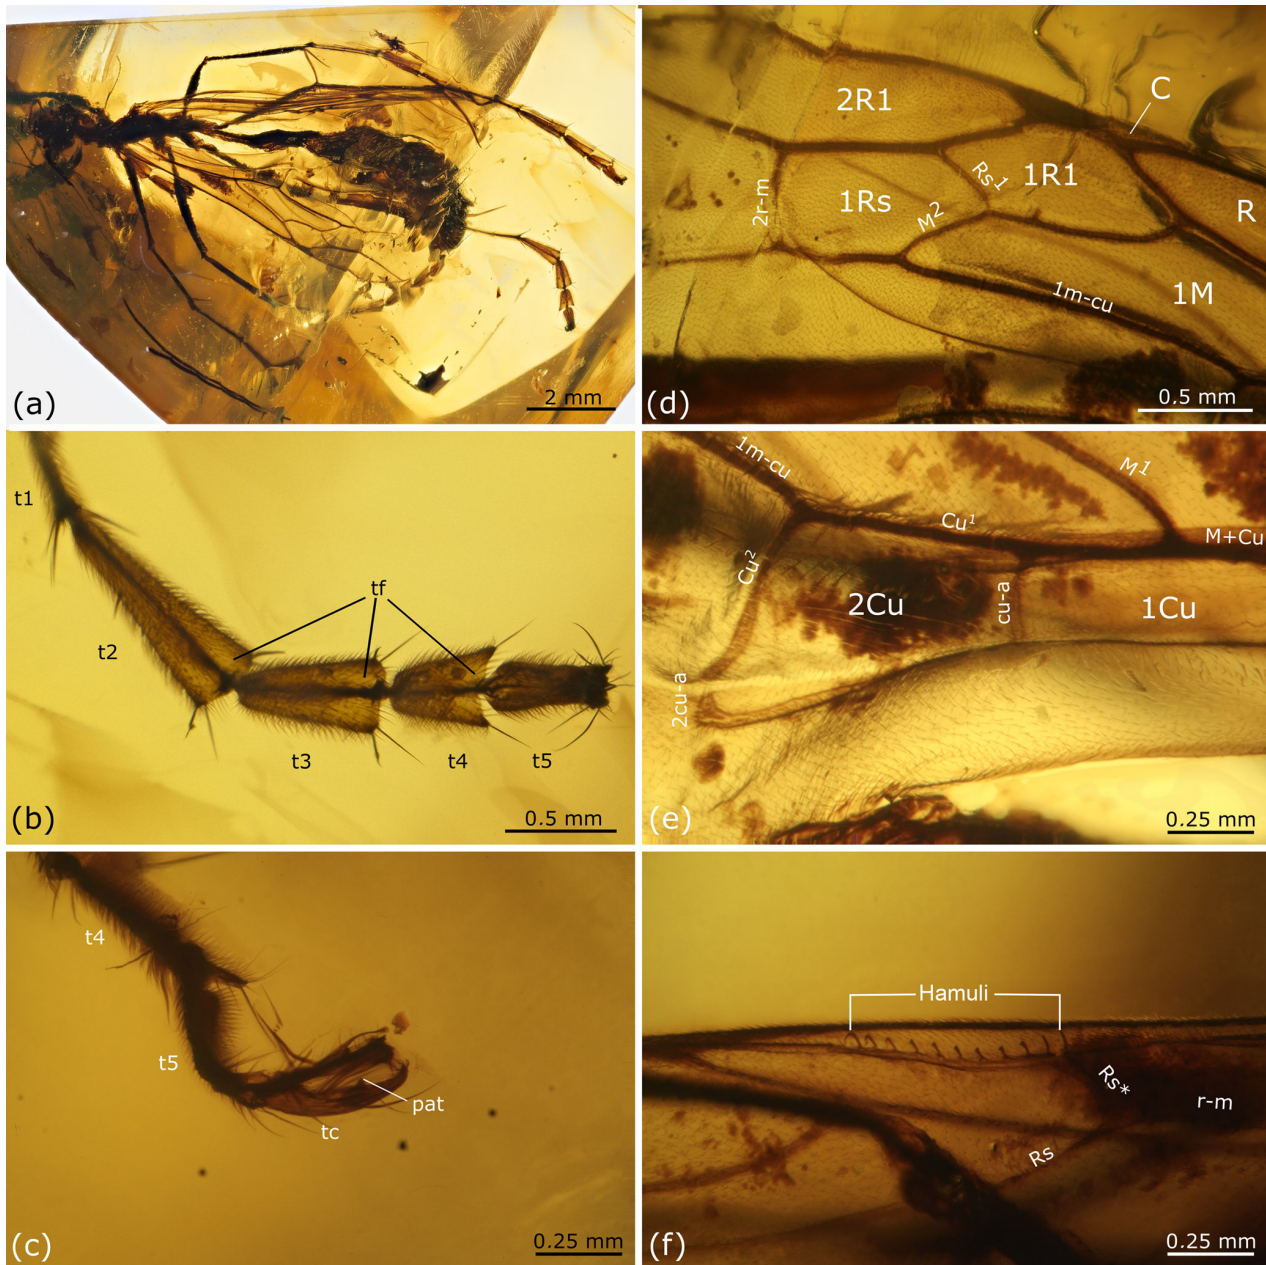

Figure 6. *Rhopalosoma* sp.: female, MB.I 6549, Miocene Mexican amber. (a) Overview. (b) Left hind tarsus. (c) Pretarsus with claws. (d–e) Details of left fore wing. (f) Details of right hind wing. Abbreviations used in (b) and (c): pat – preapical tooth, tc – tarsal claw, tf – tarsal fenestrae, t1 – tarsomere 1, t2 – tarsomere 2, t3 – tarsomere 3, t4 – tarsomere 4, and t5 – tarsomere 5.

Rhopalosoma sp.

(Fig. 6)

Material

Female, MB.I 6549, in Miocene amber from Chiapas, Mexico; the specimen is deposited in the amber collection of the Museum für Naturkunde Berlin. The specimen is almost completely preserved, except for part of the antennae, but it

is largely distorted, except for the wings and legs. In order to access the crucial characters of the fossil the amber piece has been cut into three fragments. The following syninclusions have been observed: one Hymenoptera (Braconidae), six Diptera, one Heteroptera, and one Thysanoptera.

Description

Head, mesosoma, and metasoma as in *R. hispaniola* except the following.

Measurements. Due to the heavy distortion of the specimen all measurements except for those of the wings, should be treated rather as an estimate of the general size. Body length (head, without antenna, plus mesosoma plus metasoma) in dorsal view 10.4 mm. Head width in dorsal view 1.4 mm. Mesosomal length in lateral view 2.9 mm. Fore wing length 8.2 mm. Hind wing length 6.3 mm.

Fore wing. IRs cell about $0.85 \times$ as long as cell 1R1. 1cu-a slightly curved, distad of M^1 by about $1.0 \times$ the length of 1cu-a. Distance between 1cu-a and M^1 about $0.7 \times$ the distance between 1cu-a and m-cu.

Hind wing. Rs^* very slightly curved (almost straight), its anterior section recurrent, meeting Sc + R at an angle of $\sim 45^\circ$, posterior section almost vertical. With 11 distal hamuli (Fig. 6f).

Note

This specimen resembles the female from Dominican amber. Unfortunately, many important characters, such as the size and position of the ocelli, form of the inner eye margin, etc., cannot be examined due to the insufficient preservation of the fossil. However, we do not include this specimen in the type series of *R. hispaniola* to emphasize its different geological origin and the slightly different wing venation as an indication of a separate distinct species which might be properly described and named after new material becomes available.

Currently, the genus is represented in Mexico only by *Rhopalosoma simile* Brues, 1943, and *R. obliquum* Townes, 1977 (Townes, 1977). However, neither of these species has a similar hind wing Rs^* .

4 Discussion

Based on the presence of a median tooth on the tarsal claws, females of *Rhopalosoma* are easily identified, and there is no doubt about the generic placement of the new species described herein. Townes (1977) divided *Rhopalosoma* into three species groups – the *isopus*, *poeyi*, and *lanceolatum* groups (comprising two, 14, and one species, respectively). Whereas the identification of *Rhopalosoma* at the species level remains a challenge, the new species likely belongs to the *poeyi* group based on the characters provided by Townes: front spur of mid tibia and hind tibia without narrow basal neck (as present in the *lanceolatum* group), and the form of tarsomere V, which is gradually tapered at its apical 0.65 (parallel-sided in the *isopus* group). Nevertheless, the new species has some affinities with a member of the *isopus* group, and with *R. minus* in particular, by having the hind wing Rs^* straight and recurrent. But because this state is also found in *Eorhopalosoma gorgyra*, all *Liosphex*, and several *Paniscomima* (Lohrmann and Ohl, 2010; Lohrmann, 2011; Volker Lohrmann, personal observation, 2014), it can be assumed that this is the plesiomorphic character state compared

to the angular or strongly bowed form found in many Recent species of *Rhopalosoma*. Townes (1977) regarded the *isopus* group as the “primitive species group”. His assumption is based on the similarities of the morphology of the fifth tarsomeres with those found in *Paniscomima*, a genus he regarded as “definitely more primitive”. Thus, the fossils likely do not represent the most archaic forms in the genus but represent either basal members of the *poeyi* group or an intermediate link between the *isopus* and the *poeyi* species group.

Note

The current contribution includes revised parts of a chapter used earlier in the PhD thesis of Volker Lohrmann, i.e., the description and discussion of the female of *R. hispaniola* (including Figs. 1d and 4b). Because the thesis includes a statement disclaiming all relevant nomenclatural acts from taxonomic use, the new taxon is formally described here to make its name available according to the ICZN (1999).

Data availability. No data sets were used in this article.

Appendix A

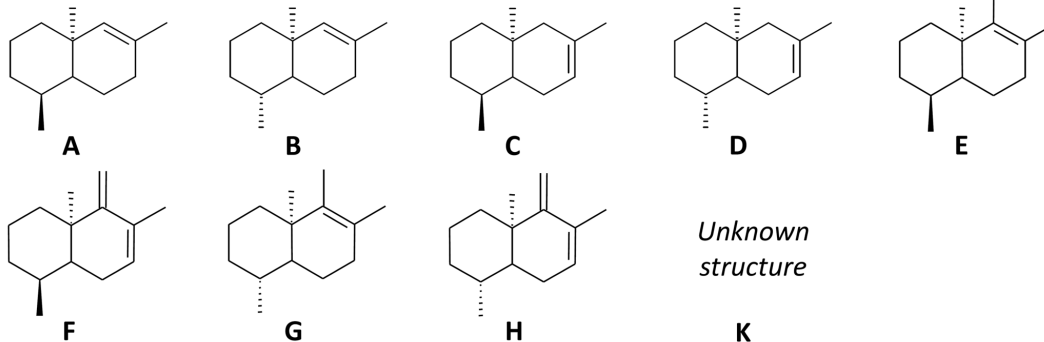

Table A1. List of identified compounds and their retention times in Mexican amber. Target compounds were identified based on m/z int and m/z identification. Areas were integrated using the m/z int, and the area on the total ion chromatogram was estimated using the mass spectra factor (MSF).

Appendix B

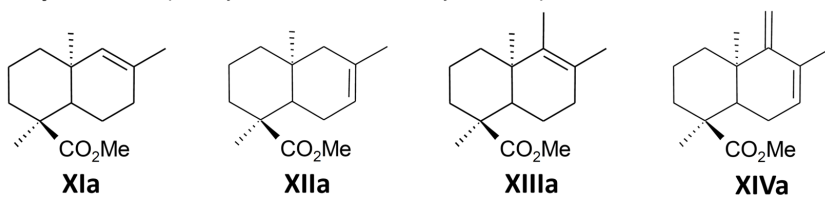

1-Methylbicyclic hydrocarbons

1-Dimethylbicyclic hydrocarbons

Bicyclic acids (analyzed as their methyl esters)

Bicyclic alcohols (analyzed free or as their methyl ethers)

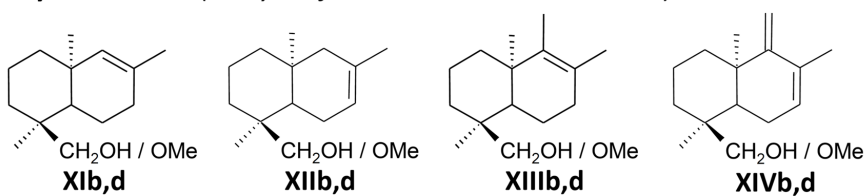

Figure B1. Molecules identified in the pyrolysates of Mexican amber. Individual compounds are labeled according to the identification of peaks in Fig. 2 and Appendix A.

Author contributions. VL designed the study. VP carried out the preparation of the fossil amber samples for the THM-GC-MS analysis and for microscopic studies of the fossils. LJ did the chemical analysis. VL prepared the species descriptions. VL, VP, and PM prepared the photographs of the fossils. VL, VP, LJ, MO, and JPP wrote the paper. All authors contributed to the discussion and proof-reading of the manuscript.

Competing interests. The authors declare that they have no conflict of interest.

Acknowledgements. We are sincerely thankful to Judy Gallagher (Woodbridge, Virginia) and Robert Lord Zimlich (Mobile, Alabama) for their kind permission to use their photographs, Jeremy Blaschke and his team (Jackson, Tennessee) for sharing their knowledge of the new host record of *Rhopalosoma*, Keith Luzzi (New Jersey) for making the two Dominican amber fossils available, and Christian Neumann (Museum für Naturkunde, Berlin) for allowing the study of all three inclusions. Partial support in the initial and the final stage of this project was provided by the “Studienstiftung des Deutschen Volkes” (to Volker Lohrmann) and the OSUR grant from program AO2 2018 for visiting researchers (to Vincent Perrichot, enabling Volker Lohrmann’s work at the University of Rennes 1) respectively. Finally, we thank Denis J. Brothers and Mónica Solórzano Kraemer for their valuable comments on the manuscript.
