ABSTRACT

Context. The Milky Way bulge is an important tracer of the early formation and chemical enrichment of the Galaxy. The abundances of different iron-peak elements in field bulge stars can give information on the nucleosynthesis processes that took place in the earliest supernovae. Cobalt ($Z = 27$) and copper ($Z = 29$) are particularly interesting.

Aims. We aim to identify the nucleosynthesis processes responsible for the formation of the iron-peak elements Co and Cu.

Methods. We derived abundances of the iron-peak elements cobalt and copper in 56 bulge giants, 13 of which were red clump stars. High-resolution spectra were obtained using FLAMES-UVES at the ESO Very Large Telescope by our group in 2000–2002, which appears to be the highest quality sample of optical high-resolution data on bulge red giants obtained in the literature to date. Over the years we have derived the abundances of C, N, O, Na, Al, Mg; the iron-group elements Mn and Zn; and neutron-capture elements. In the present work we derive abundances of the iron-peak elements cobalt and copper. We also compute chemodynamical evolution models to interpret the observed behaviour of these elements as a function of iron.

Results. The sample stars show mean values of $[\text{Co}/\text{Fe}] \sim 0.0$ at all metallicities, and $[\text{Cu}/\text{Fe}] \sim 0.0$ for $[\text{Fe}/\text{H}] \geq -0.8$ and decreasing towards lower metallicities with a behaviour of a secondary element.

Conclusions. We conclude that $[\text{Co}/\text{Fe}]$ varies in lockstep with $[\text{Fe}/\text{H}]$, which indicates that it should be produced in the alpha-rich freezeout mechanism in massive stars. Instead $[\text{Cu}/\text{Fe}]$ follows the behaviour of a secondary element towards lower metallicities, indicating its production in the weak s-process nucleosynthesis in He-burning and later stages. The chemodynamical models presented here confirm the behaviour of these two elements (i.e. $[\text{Co}/\text{Fe}]$ vs. $[\text{Fe}/\text{H}] \sim \text{constant}$ and $[\text{Cu}/\text{Fe}]$ decreasing with decreasing metallicities).

Key words. stars: abundances – Galaxy: bulge – Galaxy: abundances – nuclear reactions, nucleosynthesis, abundances – stars: late-type

1. Introduction

The detailed study of element abundances in the Milky Way bulge can inform on the chemical enrichment processes in the Galaxy, and on the early stages of the Galaxy formation. Field stars in the Galactic bulge are old (Renzini et al. 2018, and references therein), and bulge globular clusters, in particular the moderately metal-poor ones, are very old (e.g. Kerber et al. 2018, 2019; Oliveira et al. 2020). The study of bulge stars can therefore provide hints on the chemical enrichment of the earliest stellar populations in the Galaxy. Abundance ratio indicators have been extensively used in the literature and interpreted in terms of nucleosynthesis typical of different types of supernovae and chemical evolution models. The studies are most usually based on the alpha-elements O, Mg, Ca, and Si, and on Al

and Ti, which behave like alpha-elements that are enhanced in metal-poor stars (e.g. Mishenina et al. 2002; Cayrel et al. 2004; Lai et al. (2008), in the Galactic bulge (e.g. McWilliam 2016; Friaça & Barbuy 2017), and elliptical galaxies (e.g. Matteucci & Brocato 1990). The alpha-element enhancement in old stars is due to a fast chemical enrichment by supernovae type II (SNII). Other independent indicators have so far been less well studied, notably iron-peak elements, s-elements, and r-elements. Ting et al. (2012) aimed to identify which groups of elements are independent indicators of the supernova type that produced them. Their study reveals two types of SNII: one that produces mainly α -elements and one that produces both α -elements and Fe-peak elements with a large enhancement of heavy Fe-peak elements, which may be the contribution from hypernovae. This shows the importance of deriving Fe-peak element abundances.

The Fe-peak elements have atomic numbers in the range $21 \leq Z \leq 32$. The lower iron group includes Sc, Ti, V, Cr, Mn, and Fe and the upper iron-group contains Co, Ni, Cu, and Zn,

[★] Observations collected at the European Southern Observatory, Paranal, Chile (ESO programmes 71.B-0617A, 73.B0074A, and GTO 71.B-0196).

and probably also Ga and Ge. Many of these elements vary in lockstep with Fe as a function of metallicity, with the exception of Sc, Ti, Mn, Cu, and Zn, and perhaps Co (e.g. Gratton 1989; Nissen et al. 2000; Sneden et al. 1991; Cayrel et al. 2004; Ishigaki et al. 2013; da Silveira et al. 2018). This occurs because most Fe is produced in SNIa, whereas some of the iron-peak elements, in particular Co and Cu, are well produced in massive stars (Sukhbold et al. 2016, and references therein).

We previously analysed the iron-peak elements Mn and Zn (Barbuy et al. 2013, 2015; da Silveira et al. 2018) in the same sample of field stars studied in the present work, as well as Sc, V, Cu, Mn, and Zn in bulge globular cluster stars (Ernandes et al. 2018). In this paper we analyse abundances of the iron-peak elements cobalt and copper. These two elements, and copper in particular, deserve attention because the nucleosynthesis processes that produce them have been discussed over the years in the literature. The production of Cu in massive stars as a secondary product was only challenged by Mishenina et al. (2002), who argued that a sum of a secondary and a primary process would be needed to explain the behaviour of $[\text{Cu}/\text{Fe}]$ versus $[\text{Fe}/\text{H}]$ in metal-poor stars. Bisterzo et al. (2004) concluded that most Cu derives from a secondary weak- s process in massive stars; a small primary contribution of $\sim 5\%$ in the Sun would be due to the decay of $^{63,65}\text{Zn}$, and this becomes dominant for $[\text{Fe}/\text{H}] < -2.0$. On the other hand, asymptotic giant branch (AGB) stars and SNIa contribute little to Cu. Pignatari et al. (2010) presented nucleosynthesis calculations showing an increased production of Cu from a weak- s process in massive stars. Romano & Matteucci (2007) concluded that Cu enrichment is due to a primary contribution from explosive nucleosynthesis in SNII, and a weak s -process in massive stars. Lai et al. (2008) data on halo stars agreed with these models.

According to Woosley & Weaver (1995, hereafter WW95), Limongi & Chieffi (2003), and Woosley et al. (2002), the upper iron-group elements are mainly synthesized in two processes: either neutron capture on iron-group nuclei during He burning and later burning stages (also called the weak s -component); or the α -rich freezeout in the deepest layers. Both cobalt and copper are produced as primary elements in the α -rich freezeout and as secondary elements in the weak s -process in massive stars. The relative efficiency of these two contributions to the nucleosynthesis of Co and Cu can be tested by deriving their abundances in the Galaxy. Abundances gathered so far, in the Galactic bulge in particular, indicate that copper behaves as a secondary element, therefore with a significant contribution from the weak s -process. Cobalt, which appears to vary in lockstep with Fe, seems instead to be mostly contributed from the α -rich freezeout mechanism (Barbuy et al. 2018a, Woosley, priv. comm.).

Very few previous analyses of iron-peak elements in Galactic bulge stars are available in the literature. For copper, Johnson et al. (2014) and Xu et al. (2019) are so far the only available data derived from moderately high-resolution spectra. For cobalt, Johnson et al. (2014) present results from moderately high-resolution spectra, Schultheis et al. (2017) from near-infrared (NIR) spectra, and Lomaeva et al. (2019) from high-resolution spectra.

Our observations are outlined in Sect. 2. In Sect. 3 we list the basic stellar parameters, report atomic constants under study for the lines of Co and Cu, and describe the abundance derivation of Co and Cu. Chemical evolution models are presented in Sect. 4. The results are discussed in Sect. 5, and conclusions are drawn in Sect. 6.

2. Observations

The present data consist of high-resolution spectra of 43 bulge red giants, chosen to have one magnitude brighter than the red clump, from ESO programmes 71.B-0617A and 73.B0074A (PI: A. Renzini) obtained with the FLAMES-UVES spectrograph (Dekker et al. 2000) at the 8.2 m Kueyen Very Large Telescope at the Paranal Observatory of the European Southern Observatory (ESO). The stars were observed in four fields, namely Baade's Window (BW) ($l=1.14^\circ$, $b=-4.2^\circ$), a field at $b=-6^\circ$ ($l=0.2^\circ$, $b=-6^\circ$), the Blanco field ($l=0^\circ$, $b=-12^\circ$), and a field near NGC 6553 ($l=5.2^\circ$, $b=-3^\circ$). Thirteen additional red clump bulge giants were observed in programme GTO 71.B-0196 (PI: V. Hill), as described in Hill et al. (2011).

The mean wavelength coverage is 4800–6800 Å. With the UVES (Ultraviolet and Visual Echelle Spectrograph) standard setup 580, the resolution is $R \sim 45\,000$ for a 1 arcsec slit width, given that the fibres are 1.0'' wide. Typical signal-to-noise ratios (S/N) obtained by considering average values at different wavelengths vary in the range $30 \leq S/N \leq 280$ per pixel in the programme stars. Here the analysis is based uniquely on the UVES spectra, but it is noteworthy that the same sample of stars was also observed with the GIRAFFE spectrograph, as part of a larger sample (Zoccali et al. 2008), with the purpose of validating their abundance analysis at the lower resolution ($R \sim 22\,000$) of GIRAFFE.

As described in Zoccali et al. (2006), Lecureur et al. (2007), and Hill et al. (2011), the spectra were reduced using the FLAMES-UVES pipeline, including bias and inter-order background subtraction, flat-field correction, extraction, and wavelength calibration (Ballester et al. 2000).

This sample of stars had the abundances of O, Na, Mg, and Al studied in Zoccali et al. (2006) and Lecureur et al. (2007). The C, N, and O abundances were revised in Friaça & Barbuy (2017). The iron-peak elements Mn and Zn were studied in Barbuy et al. (2013, 2015) and da Silveira et al. (2018), and heavy elements in van der Swaelmen et al. (2016). In summary, the abundances of C, N, O, Na, Mg, Al, Mn, Zn, and heavy elements were derived. Gonzalez et al. (2011) derived abundances of Mg, Si, Ca, and Ti for a GIRAFFE counterpart of the sample, obtained at $R \sim 22\,000$. da Silveira et al. (2018) derived O and Zn from GIRAFFE data in two fields.

It is interesting to note that this data set, including both the high-resolution UVES data as well as the moderately high-resolution GIRAFFE data, has become an important reference for bulge studies; from this same ESO programme, Johnson et al. (2014) analysed GIRAFFE data for 156 red giants in the Blanco and near-NGC 6553 fields, and Xu et al. (2019) reanalysed 129 of these same stars. Jönsson et al. (2017) reanalysed UVES spectra of a sub-sample of 33 stars from our sample of 43 red giants, and additionally analysed two other stars, BW-b1 and B2-b8, that were observed but not included in the studies by Zoccali et al. (2006, 2008). A comparison of stellar parameters between Zoccali et al. (2006) and Lecureur et al. (2007) relative to Jönsson et al. (2017) is discussed in da Silveira et al. (2018). The same sub-sample that was reanalysed by Jönsson et al. (2017) was further analysed by Forsberg et al. (2019), Lomaeva et al. (2019), and Grisoni et al. (2020) for different elements, adopting their own stellar parameters. Finally, Schultheis et al. (2017) compared APOGEE (Apache Point Observatory Galactic Evolution Experiment) results with stars in common with Zoccali et al. (2008)'s results for stars observed with GIRAFFE.

3. Abundance analysis

The stellar parameters effective temperature (T_{eff}), gravity ($\log g$), metallicity ($[\text{Fe}/\text{H}]^1$), and microturbulence velocity (v_t) are adopted from our previous determinations (Zoccali et al. 2006, 2008; Lecureur et al. 2007), which we summarize below.

The *VIIKH* de-reddened magnitudes were combined to obtain photometric temperatures from $V-I$, $V-J$, $V-H$, and $V-K$ colours. The mean of the four values was used as a first guess for a spectroscopic analysis. Photometric gravity was calculated from the classical relation

$$\log g_* = 4.44 + 4 \log \frac{T_*}{T_{\odot}} + 0.4(M_{\text{bol}} - 4.75) + \log \frac{M_*}{M_{\odot}},$$

adopting $T_{\odot} = 5770$ K, $M_* = 0.85 M_{\odot}$, $M_{\text{bol}\odot} = 4.75$, and a mean distance of 8 kpc for the Galactic bulge.

The equivalent widths for selected lines of Fe, Na, Mg, Al, Si, Ca, Sc, Ti, and Ni were measured using the code DAOSPEC (Stetson & Pancino 2008). The selection of clean Fe lines and their atomic parameters was compiled using a spectrum of μ Leo as reference (Lecureur et al. 2007).

The local thermodynamic equilibrium (LTE) abundance analysis was performed using an updated version of the code ABON2 (Spite 1967) and MARCS models (Gustafsson et al. 2008). Excitation equilibrium was imposed on the Fe I lines in order to refine the photometric T_{eff} , while photometric gravity was imposed even if ionization equilibrium was not fulfilled.

Elemental abundances were obtained through line-by-line spectrum synthesis calculations. The calculations of synthetic spectra were carried out using the PFANT code described in Barbuy et al. (2018b), where molecular lines of the CN $A^2\Pi-X^2\Sigma$, C_2 Swan $A^3\Pi-X^3\Pi$ and TiO $A^3\Phi-X^3\Delta \gamma$, and $B^3\Pi-X^3\Delta \gamma'$ systems are taken into account. The MARCS model atmospheres are adopted (Gustafsson et al. 2008).

3.1. Line parameters: hyperfine structure, oscillator strengths, and solar abundances

We derive cobalt and copper abundances for the 56 sample stars using the lines of Co I and Cu I reported in Table 1. The oscillator strengths and the hyperfine structure (HFS) we adopted are described below.

Cobalt: Co I lines

Cobalt has the unique species ^{59}Co (Asplund et al. 2009). The HFS was taken into account by applying the code made available by McWilliam et al. (2013) together with the A and B constants reported in Table A.1 that were adopted from Pickering (1996). Cobalt has a nuclear spin $I = 7/2$. Central wavelengths and excitation potential values from Kurucz (1993)², the oscillator strengths from Kurucz (1993), NIST³ (Martin et al. 2002), and VALD (Piskunov et al. 1995), and the final values adopted are presented in Table 1.

Tables A.2–A.4 show the HFS components of the Co I lines studied. All these lines were checked by comparing synthetic spectra to high-resolution spectra of the Sun (using the same instrument settings as the present sample of spectra⁴), Arcturus (Hinkle et al. 2000), and the metal-rich giant

¹ Here we adopted the usual spectroscopic notation, that $[A/B] = \log(N_A/N_B)_* - \log(N_A/N_B)_{\odot}$ and $\epsilon(A) = \log(N_A/N_B) + 12$ for both elements A and B.

star μ Leo (Lecureur et al. 2007). We adopted the following stellar parameters: effective temperature (T_{eff}), surface gravity ($\log g$), metallicity ($[\text{Fe}/\text{H}]$), and microturbulent velocity (v_t) of (4275 K, 1.55, -0.54, 1.65 km.s^{-1}) for Arcturus from Meléndez et al. (2003), and (4540 K, 2.3, +0.30, 1.3 km.s^{-1}) for μ Leo from Lecureur et al. (2007). The adopted abundances for the Sun, Arcturus, and μ Leo are reported in Table 2.

Copper: Cu I lines

Copper abundances were derived from the two Cu I lines at 5105 and 5218 Å already employed and described in detail in ErnanDES et al. (2018). The 5782 Å line is not available in the UVES spectra. Isotopic fractions of 0.6894 for ^{63}Cu and 0.3106

for ^{65}Cu (Asplund et al. 2009), as well as the HFS structure as given in ErnanDES et al. (2018), are adopted.

Figures C.1 and C.2 show the fits to the spectra of the Sun, Arcturus, and μ Leo. The Cu I atomic parameters and fits to these reference stars were already extensively discussed in ErnanDES et al. (2018).

3.2. Results and non-local thermodynamic equilibrium corrections

The abundances derived line-by-line are reported in Table 3. The final mean abundances are given in the last three columns of Table 4, where the final mean values of [Cu/Fe] and [Co/Fe] in LTE and NLTE-corrected are reported.

Table 4. Atmospheric parameters and radial velocities adopted from Zoccali et al. (2006) and Lecureur et al. (2007), and resulting Co and Cu abundances.

| Star | OGLE no. | α (J2000) | δ (J2000) | T_{eff} | $\log g$ | [Fe/H] | v_t | v_r | v_{helio} | [Cu/Fe] _{LTE} | [Co/Fe] _{LTE} | [Co/Fe] _{NLTE} |
|--------|----------|------------------|------------------|------------------|----------|--------|----------------------|----------------------|----------------------|------------------------|------------------------|-------------------------|

Fig. 1. Fits of synthetic spectra to the eight observed lines of Co I in star BWc-4. The dotted line is the observed spectrum. The green lines correspond to the value adopted, and with $[\text{Co/Fe}] = +0.09$ and -0.09 .

Fig. 2. Fits of synthetic spectra to the two observed lines of Cu I in star BL-7. The dotted line is the observed spectrum. The green lines correspond to the value adopted, and with $[\text{Cu/Fe}] = +0.12$ and -0.12 .

Figure 1 shows the fit to the eight Co I lines in star BWc-4. Figure 2 shows the fit to the Cu I 5105.537 and 5218.197 Å lines for star BL-7.

We applied the NLTE corrections for each cobalt line following the same method used by Kirby et al. (2018), with the formalism of Bergemann & Cescutti (2010) and Bergemann et al. (2010)⁵. The derivation of corrections from the online code made available requires the choice of atmospheric model, inclusion of stellar parameters of each star, and the line list, followed by the atomic number (Z) under study. The corrections so derived line-by-line for the Co abundances are reported in Table B.1, and final NLTE-corrected Co abundance values are given in Table 4.

3.3. Uncertainties

As with our previous papers regarding this sample of spectra, and given that the final adopted atmospheric parameters for the program stars were based on Fe I and Fe II lines together with photometric gravities, we have adopted their estimated uncertainties in the atmospheric parameters (i.e. ± 100 K for temperature, ± 0.20 for surface gravity, and ± 0.20 kms^{-1} for microturbulent velocity). In Table 5 we compute Co and Cu abundances for the metal-rich star B6-f8 and the metal-poor star BW-f8 by changing their parameters by these amounts.

⁵ http://nlte.mpia.de/gui-siuAC_secE.php

Table 5. Abundance uncertainties for the metal-rich star B6-f8 and the metal-poor star BW-f8 for uncertainties of $\Delta T_{\text{eff}} = 100$ K, $\Delta \log g = 0.2$, and $\Delta v_t = 0.2$ km s^{-1} , and corresponding total error.

| Element | ΔT | $\Delta \log g$ | Δv_t | $(\sum x^2)^{1/2}$ |
|---------|------------|-----------------|-----------------------|--------------------|
| (1) | 100 K | 0.2 dex | 0.2 kms^{-1} | (5) |
| B6-f8 | | | | |
| [Co/Fe] | +0.09 | +0.01 | +0.01 | 0.09 |
| [Cu/Fe] | +0.12 | +0.02 | +0.00 | 0.12 |
| BW-f8 | | | | |
| [Co/Fe] | +0.03 | +0.00 | +0.00 | 0.03 |
| [Cu/Fe] | +0.10 | +0.00 | -0.02 | 0.10 |

Notes. The errors are to be added to reach the reported abundances.

For comparison purposes, we have listed the stars that were also analysed by Johnson et al. (2014) and Jönsson et al. (2017) in Table 6, reporting the respective stellar parameters they adopted. Johnson et al. (2014) analysed their corresponding GIRAFFE spectra, while Jönsson et al. (2016) reanalysed the same UVES data as Zoccali et al. (2006, 2008) and Lecureur et al. (2007); these data and stellar parameters given in Lomaeva et al. (2019) are the same as in Jönsson et al. (2017).

The differences in stellar parameters between the present ones adopted from Zoccali et al. (2006, 2008), Lecureur et al. (2007), and the reanalysis by Jönsson et al. (2017) were discussed in da Silveira et al. (2018). As reported in Sect. 3, the present parameters (see Sect. 3) were obtained by applying excitation equilibrium imposed on the Fe I lines in order to refine the photometric T_{eff} , and photometric gravity was imposed.

The Lomaeva et al. (2019) parameters, adopted from Jönsson et al. (2017), were obtained by using the software Spectroscopy Made Easy (SME; Valenti & Piskunov 1996). The SME software simultaneously fits stellar parameters and/or abundances by fitting calculated synthetic spectra to an observed spectrum. All the stellar parameters (T_{eff} , $\log g$,

[Fe/H], and v_t) were derived simultaneously using relatively weak, unblended Fe I, Fe II, and Ca I lines and gravity-sensitive Ca I-wings.

In the mean, the differences in parameters amount to ΔT_{eff} (Jönsson+17-Zoccali+06) = -94 K in effective temperatures and $\Delta \log g$ (Jönsson+17-Zoccali+06) = +0.46 in gravities. The gravities adopted by Jönsson et al. (2017) are possibly too high because the sample stars were chosen to have one magnitude brighter than the red clump or horizontal branch. It is well known that the red clump stars have rather homogeneous gravity values of $\log g \sim 2.2$ that can go up to $\log g \sim 2.5$ at most, depending on metallicity (Girardi 2016), and should be around $\log g \sim 2.3$ for the present metallicities. Therefore, it appears natural that red giants located at one magnitude above the red clump should have gravities around $\log g \sim 2.0$ (or lower). On the other hand, the patchy extinction towards the bulge might arguably accommodate larger gravities for the sample stars, as assumed by Jönsson

et al. (2017). In any case, we prefer to keep the parameters from our group for the sake of homogeneity of elemental abundances between this paper and the previous ones. Furthermore, since we have 56 stars, including 33 in common with Jönsson et al. (2017), it is also important to have an internal consistency in the analysis of the 56 stars.

A check of lines used by each author can explain some differences in the results, as follows. (i) Comparison of lines used for cobalt: Johnson et al. (2014) used the Co I 5647.23 and 6117.00 Å lines. Lomaeva et al. (2019) only used the UVES spectra from the red arm and relied on the Co I 6005.020, 6117.000, 6188.996, and 6632.430 Å. We have used lines from both the red arm and the blue arm spectra, as listed in Table 1; (ii) comparison of lines used for copper: Johnson et al. (2014) and Xu et al. (2019) used the same Cu I 5782.11 Å line for the same stars, which is a well-known suitable line with identified HFS structure.

4. Chemical evolution models

We have computed chemodynamical evolution models for cobalt and copper for a small classical spheroid with a baryonic mass of $2 \times 10^9 M_{\odot}$ and a dark halo mass $M_H = 1.3 \times 10^{10} M_{\odot}$, with the same models presented in [Barbuy et al. \(2015\)](#) and [Friaça & Barbuy \(2017\)](#). The code allows for inflow and outflow of gas, treated with hydrodynamical equations coupled with chemical evolution.

As described in detail in [Friaça & Barbuy \(2017\)](#), metallicity dependent yields from SNe II, SNe Ia, and intermediate mass stars (IMS) are included. The core-collapse SNII yields are adopted from WW95. For lower metallicities we also adopt, in a second calculation, yields from high explosion-energy hypernovae from [Nomoto et al. \(2013\)](#), and references therein). Yields of SNIa resulting from Chandrasekhar mass white dwarfs are taken from [Iwamoto et al. \(1999\)](#), namely their models W7 (progenitor star of initial metallicity $Z = Z_{\odot}$) and W70 (initial metallicity $Z = 0$). The yields for IMS ($0.8\text{--}8 M_{\odot}$) with initial $Z = 0.001, 0.004, 0.008, 0.02,$ and 0.4 are from [van den Hoek & Groenewegen \(1997\)](#) (variable η_{AGB} case).

Specific star formation rates (SFR) are defined as the inverse of the timescale for the system formation, represented by ν_{SF} and given in Gyr^{-1} . It is the ratio of the SFR in $M_{\odot} \text{Gyr}^{-1}$ over the gas mass in M_{\odot} available for star formation. In the present models we assume $\nu_{\text{SF}} = 3$ and 1Gyr^{-1} , corresponding to fast timescales of 0.3 and 1Gyr , respectively, for the chemical enrichment of the bulge.

The model calculations overplotted to the data are shown in Fig. 3. Models where only the WW95 yields for massive stars are included are shown in black, together with a specific star formation rate of 3Gyr^{-1} . The models in green have a specific star formation rate of 1Gyr^{-1} and adopting yields from hypernovae ([Kobayashi et al. 2006](#); [Nomoto et al. 2013](#)) instead of yields from WW95 for metallicities lower than $[\text{Fe}/\text{H}] < -4.0$. We have concluded that for these elements (Co, Cu) the inclusion of hypernovae makes essentially no difference. Since the yields from core-collapse SNII by WW95 underestimate the Co abundance, as recognized by [Timmes et al. \(1995\)](#), we have multiplied the yields of Co by a factor of two for all metallicities Z/Z_{\odot} .

In Fig. 3 $[\text{Co}/\text{Fe}]$ versus $[\text{Fe}/\text{H}]$ is shown with the present results in LTE and corrected for NLTE in the upper panel; $[\text{Cu}/\text{Fe}]$ versus $[\text{Fe}/\text{H}]$ is shown in the lower panel. Literature data include: (a) [Johnson et al. \(2014\)](#) and (b) [Xu et al. \(2019\)](#), where stars are the same but they are plotted as if there were different samples; (c) [Lomaeva et al. \(2019\)](#) only for the stars not in common with the present sample, which are 11 stars from the SW field (see [Jönsson et al. 2017](#)). We do not plot the stars in common with the present work in order to avoid too much clutter in the plot; (d) [Ernandes et al. \(2018\)](#) for bulge globular clusters.

In conclusion, Co is well reproduced by the models, whereas Cu is overproduced. Chemical evolution models from [Kobayashi et al. \(2006\)](#) show a similar Co abundance compatible with the observations, and also overproduce Cu.

5. Discussion of results

Our main interest in the present work is to compare the behaviour of cobalt and copper. They are produced both in the alpha-rich freezeout as primary elements ([Sukhbold et al. 2016](#)) and in the weak-s process in massive stars as secondary elements. The iron-peak elements are mainly formed during explosive oxygen and silicon burning in massive supernovae (WW95). For the

larger values of the neutron fraction η , the main products of silicon burning are completed. On the other hand, if the density is low and the supernova envelope expansion is fast, α particles will be frozen and not captured by the heavier elements ([Woosley et al. 2002](#)). This so-called α -rich freezeout will produce ^{59}Co . As pointed out by S. Woosley (priv. comm.) and [Barbuy et al. \(2018a\)](#), their abundances as a function of Fe can reveal the relative efficiencies of these two contributions.

In thick-disc and halo stars, [Nissen et al. \(2000\)](#), [Cayrel et al. \(2004\)](#), and [Ishigaki et al. \(2013\)](#), among others, derived abundances of iron-peak elements. [Nissen et al. \(2000\)](#) observed that Sc might be enhanced in metal-poor stars, and that Mn decreases with decreasing metallicities. [Ishigaki et al. \(2013\)](#) has also shown that most Fe-peak elements show solar abundance ratios as a function of metallicity, with the exception of Mn, Cu, and Zn. In particular as regards Co and Cu, [Ishigaki et al.](#) finds that Co varies in lockstep with Fe for $[\text{Fe}/\text{H}] > -2.0$, but appears enhanced for $[\text{Fe}/\text{H}] < -2.0$, as previously already found by [Cayrel et al. \(2004\)](#), and that Cu decreases with decreasing metallicities. [Barbuy et al. \(2013, 2015\)](#) and [da Silveira et al. \(2018\)](#) derived Mn and Zn for the present sample of 56 UVES spectra of red giants, and confirmed that Mn decreases with decreasing metallicity and that Zn is enhanced in metal-poor stars. [Ernandes et al. \(2018\)](#) discussed Sc, V, Mn, Cu, and Zn in bulge globular-cluster stars from UVES spectra, with Sc and V varying in lockstep with Fe; Mn, Cu, increasing with metallicity; and Zn enhanced in metal-poor stars. We will now examine the $[\text{Co}/\text{Fe}]$ and $[\text{Cu}/\text{Fe}]$ versus $[\text{Fe}/\text{H}]$ behaviour.

Before drawing conclusions, we present literature results here on Co and Cu in bulge stars. [Johnson et al. \(2014\)](#) derived abundances of Cr, Co, Ni, and Cu in 156 giants, and [Xu et al. \(2019\)](#) derived Cu abundances for 129 of these same stars, applying NLTE corrections. Recently, [Lomaeva et al. \(2019\)](#) derived Sc, V, Cr, Mn, Co, and Ni for bulge giants that include 33 stars in common using the same UVES data as the present sample. [Schultheis et al. \(2017\)](#) derived abundances of Cr, Co, Ni, and Mn from APOGEE results, which show, however, a large spread and are not considered here.

5.1. Comments on results for cobalt

Figure 3 shows that $[\text{Co}/\text{Fe}]$ varies in lockstep with $[\text{Fe}/\text{H}]$, and this appears in all samples. It appears therefore that the nucleosynthesis process dominating the formation of cobalt is the alpha-rich freezeout.

Figure 3 shows that the mean $[\text{Co}/\text{Fe}]$ value differs among the different authors. The [Johnson et al. \(2014\)](#) and [Lomaeva et al. \(2019\)](#) results are in the mean 0.2 dex more Co-rich than the present results. A main reason for the discrepancies might be the location of continuum. In order to further investigate the disagreement on the level of Co deficiency or over-enhancement, it is interesting to note the deficiency in Co relative to Fe in the Sagittarius dwarf galaxy. In Fig. 4 we compare the present results for Co in LTE and NLTE, compared with Co abundances in 158 red giants of the Sagittarius dwarf galaxy by [Hasselquist et al. \(2017\)](#). These authors used the H -band from APOGEE data and found that Co is deficient with respect to stars in the Milky Way. [Hasselquist et al. \(2017\)](#) did not consider NLTE effects; therefore, we compare our results in LTE and theirs, which leads to a difference in Co abundances of $\Delta[\text{Co}/\text{Fe}] \sim 0.3$, reduced by 0.2 with respect to results by [Johnson et al. \(2014\)](#) and [Lomaeva et al. \(2019\)](#). Therefore, the deficiency of Co in Sagittarius relative to the present paper is not as drastic as in previous results discussed in the literature. A possible explanation

Fig. 3. *Upper panel:* $[Co/Fe]$ vs. $[Fe/H]$ with the present results in LTE and corrected for NLTE, together with literature data. *Lower panel:* $[Cu/Fe]$ vs. $[Fe/H]$ with the present results and literature data. Shown are: the present results in LTE (open green circles); present results in NLTE (open magenta circles); Johnson et al. (2014) (filled blue circles); Lomaeva et al. (2019) for the SW field (open cyan circles); Xu et al. (2019) in LTE (open Indian red triangles); Xu et al. (2019) in NLTE (filled Indian red triangles); Ernandes et al. (2018) for bulge globular clusters (open dark orange squares) and chemodynamical evolution models are overplotted; specific star formation rates of 3 Gyr^{-1} , with SNII yields from WW95 (black lines); specific star formation rates of 1 Gyr^{-1} , with SNII yields from WW95 and from Kobayashi et al. (2006) for $[Fe/H] < -4.0$ (green lines). Models are for distances to the Galactic center of: $r < 0.5 \text{ kpc}$ (solid lines), $0.5 < r < 1 \text{ kpc}$ (dotted lines), $1 < r < 2 \text{ kpc}$ (dashed lines), and $2 < r < 3 \text{ kpc}$ (dash-dotted lines).

of the deficiency in Co in Sagittarius, previously already suggested by McWilliam et al. (2013), is that Sagittarius was less enriched by SNe II relative to the Milky Way, which could be caused by a top-light initial mass function.

5.2. Comments on results for copper

In Fig. 3 all data agree on $[Cu/Fe]$ versus $[Fe/H]$ having a flat behaviour between $-0.8 < [Fe/H] < +0.1$. For $[Fe/H] < -0.8$, copper-to-iron clearly decreases with decreasing metallicity, indicating the behaviour of a secondary element. For the metal-rich stars, our data would be compatible with a flat trend, or a slightly decreasing trend with metallicity, but this is not shown in the Johnson et al. (2014) and Xu et al. (2019) results.

Finally, there is a shift in enhancements between Johnson et al. (2014) and Xu et al. (2019). Since they use the same spectra of the same stars, and the same line, this could be due to a different placement of continua. Our results fit the abundance values from Xu et al. (2019) better and we note that the NLTE corrections from Xu et al. (2019) are small.

The behaviour of $[Cu/Fe]$ versus $[Fe/H]$, which shows a decrease in $[Cu/Fe]$ towards decreasing metallicities, confirms that $[Cu/Fe]$ essentially has a secondary-element behaviour and that its production should be dominated by a weak s-process. Another characteristic, as noted by McWilliam (2016), is that $[Cu/O]$ has much less spread than $[Cu/Fe]$ data, indicating a production of Cu and O in the same massive stars. This is confirmed in Fig. 5, where our data are plotted in NLTE together with data

Fig. 4. [Co/Fe] vs. [Fe/H]: present results in LTE and corrected for NLTE, compared with data from [Hasselquist et al. \(2017\)](#) for the Sagittarius dwarf galaxy. Symbols: open green circles represent present results in LTE; red circles represent present results in NLTE; filled blue dots represent [Hasselquist et al. \(2017\)](#).

Fig. 5. [Cu/O] vs. [Fe/H] for the present results in NLTE and literature data. Symbols: open magenta circles represent present results in NLTE; filled blue dots represent [Johnson et al. \(2014\)](#); open orange squares represent [ErnanDES et al. \(2018\)](#).

from [Johnson et al. \(2014\)](#) and [ErnanDES et al. \(2018\)](#), the latter corresponding to red giants in bulge globular clusters. It is clear that the spread of points is lower, confirming the suggestion by [McWilliam \(2016\)](#).

6. Conclusions

We derived the abundances of the iron-peak elements Co and Cu in 56 red giants of the Galactic bulge, for which we have previously derived abundances of C, N, O, Na, Mg, Al, Mn, Zn, and heavy elements. The abundances of C, N, O, Na, Mg, Al, Mn, Co, Cu, and Zn are gathered in [Table D.1](#).

Cobalt and copper are in the so-called upper iron-group. The upper iron-group elements Co, Ni, Cu, Zn, Ga, and Ge with $27 \leq Z \leq 32$, or $57 \leq A \leq 66$ (up to ^{66}Zn , but excluding $^{67,68}\text{Zn}$, ^{69}Ga , $^{70,71}\text{Ge}$) are mainly produced in two processes, namely, a) neutron capture on iron-group nuclei during He burning and later burning stages, also called weak *s*-component, and b) the α -rich freezeout in the deepest layers ([Woosley et al. 1973](#)), also discussed in WW95, [Limongi & Chieffi \(2003\)](#), [Woosley et al. \(2002\)](#), and [Sukhbold et al. \(2016\)](#). The nucleosynthesis yields from the weak *s*-component show a characteristic secondary behaviour.

In this work we analysed a sample of high-quality spectroscopic data for 56 Galactic bulge red giants. The present results show $[\text{Co}/\text{Fe}] \sim \text{constant} \sim 0.0$, indicating cobalt mainly produced from the α -rich freezeout. Copper instead shows a secondary element behaviour, with $[\text{Cu}/\text{Fe}]$ decreasing with decreasing metallicity, indicating its production to be dominated by the weak *s*-process. The yields of Co and Cu considered in the models appear to include these two mechanisms in the right

proportions, and the chemodynamical models reproduce their behaviour well.

Appendix A: Atomic data

The hyperfine structure constants of Co I and Cu I lines employed in this work are given in Table A.1. In Tables A.2, A.3, and A.4,

the lines of Co I in terms of their HFS components, and corresponding oscillator strengths, are listed.

Table A.1. Atomic constants for Co I and Cu I used to compute hyperfine structure: A and B constants from Pickering (1996) for Co I. For Cu I, the A and B constants are from Kurucz (1993) and Biehl (1976), and they are reported in Ernandes et al. (2018).

Appendix B: NLTE corrections to cobalt abundances

The NLTE corrections to the derived LTE abundances of Co, derived from calculations made available online by [Bergemann et al. \(2010\)](#) (see text), are given in Table B.1.

Table B.1. NLTE corrections to the derived LTE abundances of Co.

| Star | [Co/Fe] 5212.691 Å | [Co/Fe] 5280.629 Å | [Co/Fe] 5301.047 Å | [Co/Fe] 5342.708 Å | [Co/Fe] 5454.572 Å | [Co/Fe] 5647.234 Å | [Co/Fe] 6117.000 Å | [Co/Fe] 6188.996 Å |

Appendix C: Fits of studied lines to the spectra of the Sun, Arcturus, and μ Leo

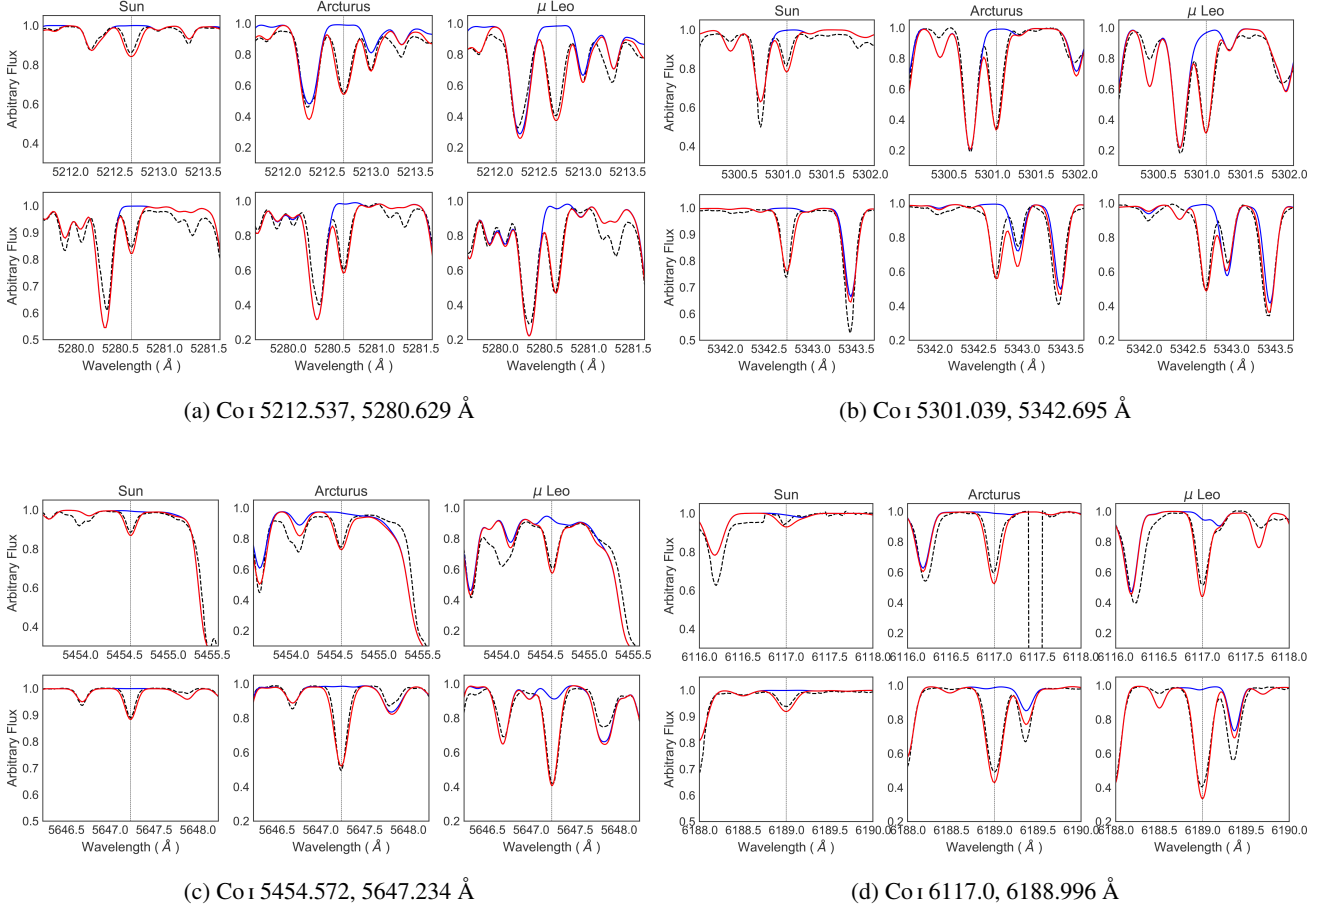

Fig. C.1. Cobalt lines as fitted to the Sun, Arcturus, and μ Leo.

Fig. C.2. Copper lines Cu I 5105.537 and 5218.197 Å, as fitted to the Sun, Arcturus, and μ Leo.

The lines of Cu I and Co I employed to derive abundances in the present work were first fitted to the spectra of the Sun, Arcturus, and μ Leo, as shown in Figs. C.1 and C.2. Details on the adopted parameters are given in Sect. 3.

Appendix D: Abundances of C, N, O, Na, Mg, Al, Mn, Co, and Cu for the 56 sampled red giants

In Table D.1, the metallicity from Zoccali et al. (2006), Lecureur et al. (2007), and Hill et al. (2011) for the 56 sample red giants is reported in Col. 2. The abundances of C, N, O, Na, Mg, Al, Mn, Co, Cu, and Zn from the following sources are reported: CNO abundances revised in Friaça & Barbuy (2017); Na, Mg, and Al from Lecureur et al. (2007); Mn from Barbuy et al. (2013); Zn from Barbuy et al. (2015) and da Silveira et al. (2018); and the present results on Co (LTE and NLTE-corrected) and Cu.

Table D.1. Metallicity [Fe/H] and abundances of C, N, O, Na, Mg, Al, Mn, Co, Cu for the 56 sample red giants.

| Star | [Fe/H] | [C/Fe] | [N/Fe] | [O/Fe] | [Na/Fe] | [Mg/Fe] | [Al/Fe] | [Mn/Fe] | [Cu/Fe] | [Co/Fe] _{LTE} | [Co/Fe] _{NLTE} | [Zn/Fe] |
|--------|--------|--------|--------|--------|---------|---------|---------|---------|---------|------------------------|-------------------------|---------|
