AUTHORS STATEMENT FOR PUBLICATION

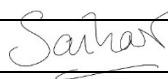

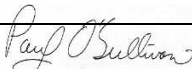

Manuscript title: **First timing constraints on the Ecuadorian Coastal Cordillera exhumation: geodynamic implications**

Corresponding author's full name: **Stephanie Brichau**

Please note that all contributing authors are obligated to sign *Authors statement for publication* form otherwise the manuscript will not be published.

Please fill in the table below according to following:

- *list the authors in order in which they are stated in manuscript. This way each author is assigned with number for further identification.*
- *each author should sign this document (on designated place in the table). By signing this form authors take full responsibility for all statements it contains.*

No.	Author's full name (in capital letters)	Author's signature
1.	Stephanie Brichau	
2.	Pedro Reyes	
3.	Cecile Gautheron	
4.	Maria José Hernandez	
5.	François Michaud	
6.	Mathieu Leisen	
7.	Arnaud Vacherat	
8.	Marianne Saillard	
9.	Jean-Noel Proust	
10.	Paul O'Sullivan	

AUTHORSHIP STATEMENT:

According to International Committee of Medical Journal Editors (ICMJE): "An author is considered to be someone who has made substantive intellectual contributions to a published study. An author must take responsibility for at least one component of the work, should be able to identify who is responsible for each other component, and should ideally be confident in their co-authors' ability and integrity. " (available at: http://www.icmje.org/ethical_1author.html)

Please fill the table with numerical code of each author (from the before signed table) regarding authors contribution to specific component of research.

Component of the research	Author's number
substantial contribution to conception and design	1, 2, 4, 5, 8, 9
substantial contribution to acquisition of data	1, 3, 6, 7, 10
substantial contribution to analysis and interpretation of data	1, 2, 3, 4, 5, 6, 7
drafting the article	1, 2, 3, 5, 7
critically revising the article for important intellectual content	1, 2, 3, 4, 5, 6, 7, 8, 9
final approval of the version to be published	1, 2, 3, 4, 5, 6, 7, 8, 9, 10

Please tick the box if the statement applies:

- to the best of your knowledge everybody who participated substantially in the study is not omitted from the article
- to the best of your knowledge, all persons listed as authors qualify for authorship

All persons who have made substantial contributions to the work but do not meet the criteria for authorship are listed in Acknowledgments section (technical help, writing assistance, general support, financial and material support)

Yes No

All persons named in the Acknowledgment section of the manuscript have given their permission to be named

Yes No

ORIGINALITY OF THE WORK STATEMENT:

Editorial board of the journal: Medical Archives; Materia Socio-medica or Acta Informatica Medica strongly promotes research integrity and aims to prevent any type of scientific misconduct according to Committee on Publication Ethics (COPE) flowcharts. (available at: <http://publicationethics.org/resources/flowcharts>)

Please tick the box if the following statements are correct to the best of your knowledge:

- the manuscript is not previously published in the same or very similar form in other journal (previous publishing does not apply to abstract or poster presentations at a professional meeting)
- the manuscript is not currently under consideration in other journals (that does not apply for manuscripts that have been rejected by other journals)

19 **ABSTRACT**

20
21 In this study, we provide the first detrital apatite (U-Th-Sm)/He (AHe) and zircon U-Pb ages
22 to establish a detailed short-term chronology of the burial and exhumation history, which
23 occurred in the Coastal Cordillera along the forearc domain of Ecuador. First, our results
24 allowed us to define a range of maximum deposition ages for the Angostura Formation from
25 9.6 ± 0.2 Ma to 11.5 ± 0.6 Ma, which records high enough temperatures to partially reset AHe
26 ages. QTQt thermal inverse modeling of the AHe dataset reveals three main periods of

27 exhumation along the Coastal Cordillera at ~2 Ma, ~5-6 Ma and ~8-10 Ma, independent of the
28 sample geographic locations. We discuss the origin of these periods of exhumation in relation
29 to the geodynamic frame. The oldest exhumation event, at ~8-10 Ma, evidenced locally along
30 fault systems, could be related to overriding plate kinematic changes or early arrival of
31 Carnegie Ridge. The intermediate exhumation period, at ~5-6 Ma, could be explained by a
32 later arrival of the Carnegie Ridge or to the subduction of an along-strike positive relief of the
33 ridge. Later, subduction of sea-floor asperities could be responsible for heterogeneous uplift
34 of the Coastal Cordillera during the Pleistocene (~2 Ma) that induced exhumation as
35 supported by our models. These results are corroborated by previous studies and demonstrate
36 that AHe data are sensitive enough to provide reliable constraints in sedimentary domains.

40

41 1. INTRODUCTION

42

43 Ongoing uplift and relief building on the overriding plate along active subduction
44 margins frequently depends on the stability of certain parameters such as slab pull, mantle
45 dynamics and absolute plate motion (Lallemand et al., 2005; Schellart et al., 2007; Cerpa and
46 Arcay, 2020), penetration and anchored of the slab into the lower mantle (Faccenna et al.,
47 2017), inherited structures of the upper plate margin (Audin et al., 2008), subduction of
48 seafloor reliefs (Zeumann and Hampel, 2016; Morell, 2016; Collot et al., 2017) and
49 subduction-erosion versus subduction-accretion behaviors (Clift and Vannucchi, 2004),
50 among others. These parameters are supposed to control the mechanical coupling between
51 plates as well as the relief generation related to forearc deformation (Noda, 2016). Building

52 topography and climate change, exert a feedback control on the sediment input into the
53 subduction channel (Horton, 2018; Saillard et al., 2017), which is thought to have a strong
54 impact on seismogenic zone behavior (Collot et al., 2011; Saffer and Tobin, 2011; Heuret et
55 al., 2012, Behr and Becker, 2018).

56 Since many processes can be responsible for the evolution of the subduction systems and the
57 stress accumulation at the plate interface, it is of prime importance to define the timing and
58 how relief generation occurs in the forearc domain to decipher which are the processes
59 involved in a specific area.

60 Along the South American Pacific margin, terrigenous sediment contribution is
61 controlled by the erosion of the Andean orogen, which induces a significant supply of
62 material to the forearc basin (Witt et al., 2017; Fig. 1). In the Ecuadorian forearc, the uplifting
63 of the Coastal Cordillera, which culminates at about 800 m above the sea level (Fig. 1), has
64 hindered the sediment pathways from the Andes, thereby enhancing sediment starvation in the
65 trench. Andean sourced sediments are currently rerouted by the northern Esmeraldas river
66 system (Collot et al., 2019), and by the southern Guayas river into the Gulf of Guayaquil
67 (Deniaud et al., 1999), crossing through the ends of the Coastal Cordillera (Fig. 1).
68 Consequently, at present-day, the resulting sedimentary fluxes supplied into the subduction
69 trench correspond with the modern river patterns draining the western slope of the Coastal
70 Cordillera. This morphotectonic effect implies a sediment starved-trench, which is expected
71 to modify the shear stress along the plate interface and to promote strong impacts on the
72 tectonic and seismogenic plate interface coupling (Cloos and Shreve, 1988; Ruff, 1989;
73 Heuret et al., 2012; Scholl et al., 2015).

74 The timing and amount of uplift throughout the Ecuadorian Coastal Cordillera, with
75 the exception of the specific littoral (Pedoja et al., 2006) and offshore (Michaud et al., 2015;
76 Proust et al., 2016; Collot et al., 2019; Hernández et al., 2020) areas, is poorly known (Reyes,

77 2013). Application of techniques based on chronometers and detrital thermochronometers,
78 usually provide quantitative constraints on relief generation and topographic growth. Here, we
79 provide the first detrital apatite (U-Th-Sm)/He and zircon U-Pb age data from the Coastal
80 Cordillera and adjacent forearc basins of Ecuador and discuss the potential processes, which
81 caused this rock cooling in the light of tectonic and the geodynamic frameworks.

82

83 **2. TECTONIC AND GEOMORPHIC SETTING OF THE COASTAL CORDILLERA**

84

85 **2.1 Geodynamic framework**

86 The Nazca plate subducts towards N83° (Nocquet et al., 2014) at a velocity of ~58
87 mm/yr (Trenkamp et al., 2002; Fig. 1) beneath the South American plate (SAP), leading to an
88 important seismic activity (Font et al., 2013; Fig 1). This oblique subduction, which involves
89 the Carnegie Ridge (a 2-km-high and 200-km-wide volcanic ridge) resulting from the
90 eastward motion of the Nazca plate over the Galapagos hotspot since ca 20 Ma (Sallarès et al.,
91 2003), is thought to control the northeastward motion of the North Andean Silver (Witt and
92 Bourgois, 2010), the subsequent opening of the Gulf of Guayaquil (Witt et al., 2006), and the
93 Ecuadorian forearc uplift (Pedoja et al., 2006; Fig.1). The timing of the ridge subduction
94 onset is highly debated ranging from 1 to 15 Ma (Lonsdale and Klitgord, 1978; Spikings et
95 al., 2001; Michaud et al., 2009; Collot et al., 2009; Schütte et al., 2010; Spikings and
96 Simpson, 2014; Michaud et al., 2018; Chiaradia et al., 2020). Several authors argue for an
97 initiation of the Carnegie Ridge-trench interaction as early as ~10-15 Ma. According to
98 Schütte et al. (2010), based on the spatio-temporal distributions of the Tertiary arc
99 magmatism ages, the eastward arc migration and arc broadening starting at ~10-12 Ma,
100 probably in response to the subduction of the Carnegie Ridge. Similarly, Spikings and
101 Simpson (2014), assume that the variation in cooling ages and exhumation depths support a

102 phase of high rates of rock uplift and exhumation around ~13–15 Ma in the Eastern Cordillera
103 of Ecuador (Spikings et al., 2001; Villagómez and Spikings, 2012). They attribute this vertical
104 displacement and exhumation to the collision and subduction of the Carnegie Ridge. For the
105 same period, Chiaradia et al. (2020) speculate that the subduction of the Carnegie Ridge could
106 have affected magmatism geochemistry as crustal thickness increase. However, for Collot et
107 al. (2009), morpho-tectonics evidences argue for the beginning of Carnegie Ridge subduction
108 at ~5 Ma. The structural segmentation of the offshore forearc domain during the early
109 Pliocene (~5.2 Ma) is tentatively associated with the arrival of the Carnegie Ridge into the
110 subduction zone and the creation of a mosaic of middle-late Pleistocene depocenters that
111 alternate with uplifted zones along the shelf that are proposed to record the subduction of the
112 topographically irregular Carnegie Ridge (Hernández et al., 2020). At the same time, incision
113 of the Esmeraldas canyon (Fig. 1) began to form in response to a boost of the forearc uplift
114 (~5.3 Ma ago) that is temporally correlated with the Carnegie Ridge subduction following by
115 two deep incisions providing evidences for uplift episodes in the mid-Pliocene and early
116 Pleistocene times (Collot et al., 2019).

117

118 **2.2 Morphostructural Segmentation**

119 The coastal forearc system of the Ecuadorian margin is organized into four
120 morphotectonic zones including: the western border of the Andes, the adjacent onshore
121 platform (currently the emerged ca. 170 km wide coastal region), the offshore platform (ca.
122 50 km wide), and the continental slope that has been partially modified by the Carnegie Ridge
123 subduction at the trench (Collot et al., 2009; Fig. 1). The onshore forearc shows three major
124 morphostructural domains: the piedmont basin (coastal plain) characterized by alluvial fan
125 development, the Coastal Cordillera, in front of the Carnegie Ridge (Fig. 1) bounding the
126 active western margin, and the Gulf of Guayaquil to the south. The northern part of the

127 coastal plain persists until the Colombian margin. Morphometric analysis along river profiles
128 suggest that the Coastal Cordillera is divided into five distinct structural blocks or domains
129 (Reyes et al., 2010; Reyes, 2013; Reyes et al., 2018).

130

131 **2.3 Stratigraphy of the fore-arc basins**

132 The Miocene sedimentary fill of the onshore coastal forearc is emplaced over pre-
133 existent sedimentary basins during the Cretaceous and the Paleogene filling cycles. The
134 Upper Cretaceous cycle is characterized by high-lithified volcanoclastics, turbidites (Cayo
135 Formation) and bedded chert sequences deposited over a thickened oceanic crust (basalts and
136 gabbros of the Piñon Formation) of middle-late Cretaceous age (Reynaud et al., 1999;
137 Luzieux et al., 2006; Vallejo et al., 2009). The Paleogene cycle comprises a basal siliciclastic
138 turbiditic sequence giving rise upsection to coarsening upward calcareous and pelitic siliceous
139 series with some volcanoclasts. The Miocene sediments have been dated by biostratigraphy
140 (Benítez, 1995; Deniaud, 2000; Ordóñez et al. 2006; Cantalamessa et al., 2007) and fill local
141 depressions separated by basement structural highs (Fig. 3). A ca. 2500 m thick pelitic and
142 diatomaceous stratigraphic succession is deposited in all the basins (stratigraphic level named
143 as Dos Bocas, Viche, Villingota Formations). This is overlain by the shallow marine 100-500
144 m thick sandy Angostura Formation (Bristow and Hoffstetter, 1977; Benitez, 1995), including
145 volcanoclastic coarse-grained turbidites indicative of a deeper marine environment (Reyes,
146 2013). The proposed age of the Angostura Formation ranges from ~9 Ma to ~15 Ma (Benítez,
147 1995; Deniaud, 2000; Ordóñez et al. 2006; Cantalamessa et al., 2007), but may be
148 diachronous. The transition to the overlying late Miocene Ónzole Formation is often
149 conformable and gradual (Deniaud, 2000), with locally, planar discontinuity (Cantalamessa et
150 al., 2007). The Ónzole Formation comprises 300 to 700 m of thick bluish grey siltstones, of
151 marine platform environment (Deniaud, 2000), passing upward with an unconformable and

152 erosional contact (Di Celma et al., 2010) to 100 to 400 m of shallow water marine coarse
153 sandstones, conglomerates and volcanoclastics of the Pliocene to Lower Pleistocene Borbón
154 Formation (Reyes, 2013; Fig. 3).

155

156 **2.4 Inversion of the fore-arc basins**

157

158 Regional stratigraphy provides a first constraint to estimate the amount of exhumation and
159 growth of the Coastal Cordillera (Fig. 2). Marine sediments of Mio-Pliocene age, deposited in
160 onshore forearc domain, dominate some of the highest areas (i.e. ~ 600 m) of the Coastal
161 Cordillera (Benítez, 1995; Deniaud, 2000) and reveal a late Neogene uplift (Evans and
162 Whittaker, 1982). The northern Borbón basin area (Esmeralda region) is exposed along
163 Mache-Chindul mountain range, which is separated from the central-south Manabí basin by
164 the EW-trending Canandé fault (Fig. 2). This southward dipping fault reveals, at first, a
165 normal displacement during the early-middle Miocene followed by a compressional activity
166 during the Pliocene, controlling the relative uplift of the Borbón basin (Hernández et al.,
167 2020). The 100 to 500 m thick massive turbidites of the Angostura Formation are preserved in
168 the two basins. The 300 to 700 m thick Ónzole and 100 to 400 m thick Borbón Formations
169 bury the Angostura Formation in this domain (Reyes, 2013). To the South, the eastward
170 dipping NE-SW-trending Jama fault system (Reyes, 2013; Reyes et al., 2018) bounds the
171 Jama massif (block) cored by oceanic plateau affinities Cretaceous rocks (pillow basalts,
172 dolerites and gabbro) of the Piñón Formation (Bristow and Hoffstetter, 1977) and surrounded
173 by the Angostura Formation (Fig. 2). Along this fault, a normal displacement during the
174 early-middle Miocene is followed by compression, underlined by an anticlinal during the
175 Pliocene (Hernández et al., 2020). In the central Manabí basin, the flat-topped Pichincha-
176 Portoviejo 400 m-high consists of sub-horizontally uplifted strata of the Borbón Formation.

177 The NNE-SSW trending sub-vertical Jipijapa fault, controls the Jipijapa massif (block, Fig.
178 2), which juxtaposes the Cretaceous rocks of the basement against the Miocene sediments of
179 the Dos Bocas Formation (Reyes et al., 2013). In the southern Manabi basin, the WNW-ESE
180 trending south-verging Chongón-Colonche fault raises the basement-cored Chongón-
181 Colonche massif (block) that separates the Manabí basin from the southern Progreso basin
182 (Fig. 2) (Reyes et al., 2013).

183

184 **2.5 Andes cooling events and sediment provenance in the fore-arc basins**

185 Detrital sediments and volcanoclastic material deposited in the forearc basin are largely
186 delivered from the Ecuadorian Andes (Deniaud, 2000). The collision-accretion history of the
187 Ecuadorian Andes initiated in the Lower Cretaceous with the accretion of tectono-
188 metamorphic terranes (Litherland et al., 1994) along the Eastern Cordillera and continued in
189 the Upper Cretaceous with the accretion of the oceanic terranes in the Western Cordillera
190 (Goossens, and Rose, 1973; Feininger and Bristow 1980; Lebrat et al. 1987; Reynaud et al.
191 1999; Kerr et al., 2002; Luzieux et al., 2006; Vallejo et al., 2009; Jaillard et al., 2004 and
192 2009). These accreted terranes recorded important magmatic (both granitoid and mafic) and
193 volcanic events from Triassic to Holocene times (Cochrane et al., 2014; Spikings et al., 2015).
194 The main recognized zircon U-Pb age peaks are ~234-207 Ma, ~182-141 Ma, and ~40-5 Ma
195 in the Northern part of Ecuadorian Andes (from 1°N to 3°S). In the southern part of the
196 Ecuadorian Andes, detrital zircon ages from the Cenozoic forearc basins in SW Ecuador
197 suggest that the Western Cordillera was already uplifted in the Paleocene (Witt et al., 2017).

198 Fission tracks analysis from this basement revealed two main periods of regional scale
199 cooling at ~13 and ~9 Ma (Spikings et al., 2005), close to the age of the Angostura Formation
200 sediments, followed by a rapid cooling and exhumation at ~5.5-0 Ma (Spikings et al., 2010).

201

202 **3. METHODOLOGY AND RESULTS**

203

204 **3.1 Method**

205 To constrain the timing of the Coastal Cordillera uplift, the strategy of sampling has
206 been defined according to geographic localizations along the coast, appropriate lithology to
207 maximize the probability to obtain apatite crystals and stratigraphic level buried enough to
208 record if not fully at least partially resetted apatite (U-Th-Sm)/He (AHe) thermochronometer.
209 Accordingly, the more adapted lithology in a sedimentary rock environment remains the
210 sandstones. Therefore, we attempted to collect 13 samples in the Angostura Formation all
211 along the Costal Cordillera (Fig. 2, Table 1), based on facies criteria since the sandstone
212 Angostura Formation is framed by two formations more fine and clayey (below the pelitic
213 Dos Bocas Formation and above the Ónzole Formation described as a siltstone). Furthermore,
214 in order to avoid mistakes about the stratigraphic level in which samples have been collected,
215 we performed U-Pb dating on zircon to determine the youngest detrital age.

216 Apatite and zircon grains were separated using standard heavy liquid and magnetic
217 separation techniques between GeoAzur (Nice, France) and Geosciences Environnement
218 Toulouse (GET, France).

219 In most samples, over 100 grains of zircon were selected for in situ U-Pb dating using
220 LA-ICPMS at GeoSep Services (Moscow, Idaho, USA) and Geosciences Environnement
221 Toulouse (GET, France) following the procedure detailed by Prudhomme et al. (2019) and
222 Kahou et al. (2020). Analytical procedure and data are reported in supplementary section
223 under the Table A.1, and A.2 and Concordia plot diagram under the Figure A.1.

224 Apatite grains were carefully selected for AHe age dating, then each crystal was
225 measured and loaded in platinum (Pt) capsules for He, U, Th, and Sm measurements at
226 GEOPS laboratory (Orsay, France), following the procedure described by Fillon et al. (2013).
227 The alpha ejection factor (F_T) and sphere equivalent radius (R_s) were calculated for each

228 crystal using Qt_{F_T} software (Gautheron and Tassan-Got, 2010; Ketcham et al., 2011).
229 Between three to ten replicates per sample, depending of the availability of quality apatite
230 grains (inclusions and cracks free, avoiding broken grains, width over 60 μm), have been
231 carried out and the results are reported in Table 2.

232 To be able to interpret and extract the thermal history of our samples, we perform
233 inversion modeling of the AHe data set using the software QTQt (Gallagher, 2012). The
234 inverse modeling was performed using the kinetic models for helium diffusion in apatite
235 crystals from Gautheron et al. (2009) that takes into account the He production and diffusion
236 in damaged apatite structure. Radiation damage accumulation depends on production during
237 U-Th and Sm decay and annealing that is a function of the crystal size chemistry and
238 temperature. The apatite grain size (R_s), He, U, Th and Sm content for each crystal of the
239 sample were used for the inversion (Table 2). The inversion procedure uses a Bayesian
240 “Markov chain Monte Carlo” algorithm to determine the best time-temperature path
241 reproducing our data through a large number (200,000) of randomly tested solutions (see
242 Gallagher (2012) for detailed modeling procedure). In order to fully exploit the thermal
243 history information contained in partially annealed samples and therefore improve the
244 resolution on the modeling, QTQt is able to model the pre-depositional thermal history of the
245 apatite grains.

246 The models were performed for a parameter space (time *t* and temperature *T*) at 40 ±
247 40 Ma and 70 ± 70 °C (red box) and a constraint at surface temperature during sediment
248 deposition time were used (15 to 5 Ma or 15 to 9 Ma, small black box). This large time box
249 before sediment deposition time allows the model to explore pre-depositional history and was
250 fixed to allow Cenozoic history. For one sample (13ECC04), where the modeling did not
251 converge correctly, we added a constraint at 70 ± 10 Ma, 60 ± 60 °C (long before the
252 deposition time and older than the oldest AHe age) to take into account all possible scenarios

253 before deposit. Samples 13ECC12A and 12B were modeled together as they are considered to
254 be a single sedimentary unit because of their close geographical location. The final model is
255 represented by a set of time-temperature histories for which we included the expected model
256 (weighted mean model, black line) and the maximum likelihood model (best data fitting
257 model, orange line). In addition, the predicted AHe ages for the expected model and the
258 maximum likelihood models obtained by QTQt are reported as a function of the observed
259 (measured) AHe ages.

260

261 **3.2 Results**

262 **3.2.1 Zircon U-Pb dating**

263 Since the purpose of zircon U-Pb dating was to constrain maximum depositional ages,
264 the number of analyses per sample is less critical than for a detailed provenance study.
265 However, we attempted to date over 100 grains to fit the recommendation of Vermeesch
266 (2004). Only in samples 12ECC05 and 18BCB02, the number of analyses is below 100 (at 29
267 and 95, respectively), due to the small amount of zircon available.

268 It is usual to filter the data set to apply a 10 to 20 % discordance cutoff with the aim of
269 avoiding data related to Pb loss processes. Yet, in the case of young ages (e.g. <100 Ma), this
270 discordant filter is not valid due to the difficulty of determining a reliable $^{206}\text{Pb}/^{207}\text{Pb}$ or
271 $^{207}\text{Pb}/^{235}\text{Pb}$ ratios (Gehrels, 2012). In our study, we collected samples in a Miocene
272 stratigraphic level, implying that the ages obtained are mostly young and therefore
273 discordancy filter is not applicable since most of the ages are highly discordance for ages
274 below 50 Ma (as shown in Table A.1 and Fig. A.1).

275 In all samples, the main age populations are Cenozoic and Cretaceous with a small
276 Precambrian contribution and sometimes, a slight additional input from Paleozoic to Triassic
277 sources (Table A.2).

278 To represent the data set for each sample and to be able to compare the youngest peak
279 ages, we have represented the results under an age-distribution diagram that includes the error
280 of each analysis (Gehrels, 2012). We choose, for better visibility of the youngest age peaks, to
281 show only the results for ages younger than 40 Ma. To define the youngest detrital zircon
282 (YDZ) age, several methods have been defined over the last decade. According to Dickinson
283 and Gehrels (2009) and Coutts et al. (2019), the best way to determine the YDZ age is to
284 calculate the weighted mean age of the youngest cluster of three or more grain ages
285 overlapping in age at 2σ uncertainty. However, for Spencer et al. (2016) and Copeland
286 (2020), the weighted mean can only be used if the zircons are from a single population, such
287 as volcanic eruption or rapidly emplaced pluton. Therefore, Spencer et al. (2016) recommend
288 practicing multiple analyses on the youngest zircon grain to assure the validity of the analysis,
289 to check the lack of correlation between U and Th content versus age to rule out potential Pb-
290 loss, and to add chemical or isotopic data such as Hf to ensure that the weighted mean has
291 been defined on a single forming-zircon event. For Copeland (2020), the best estimate will be
292 to use the youngest single concordant grain and not an averaging of data. We did not perform
293 additional analyses to ensure the single population origin of our zircons since the purpose of
294 these analyses is only to verify if our samples have been collected in the correct formation
295 (Angostura). However, no correlation between U or Th and ages has been observed (Table
296 A.2) and we followed the recommendation of Copeland (2020) and reported in table 3 the
297 YDZ and the youngest concordant (discordancy below 15%) single grain (YCSG) ages. All
298 results are similar within errors, except for sample 18BCB02 which presents low U content
299 and almost no concordant ages (only two data are below 15% of discordancy, see Table A.2).
300 Since the purpose of these analyses is only to verify if our samples have been collected in the
301 correct formation (Angostura with youngest depositional age estimated at ~9 Ma) and owing
302 to the fact that YDZ and YCSG ages are similar within errors and the ages are young with

303 low U content, it seems more appropriate here to use the YDZ ages which have been
304 obtained, as the age-distribution diagrams, using the routine available from
305 www.geo.arizona.edu/alc (Table 3 and Fig. 4).

306 Two samples, 12ECC05 and 12ECC07, show clearly younger peak ages than expected
307 for Angostura Formation (YDZ ages at 7.0 ± 0.3 Ma and 7.1 ± 0.2 Ma, respectively),
308 indicating that they belong to the Ónzole Formation, from its lowest level. The YDZ age for
309 sample 18BCB02 seems to be slightly older than 12ECC05 and 07, at 7.7 ± 0.1 Ma, and
310 maybe close to the limit between Angostura and Ónzole Formation. For all the other samples,
311 the YDZ range from 9.6 ± 0.2 Ma to 11.5 ± 0.5 Ma corresponding to the range of the
312 depositional ages of the Angostura Formation (Benítez, 1995; Deniaud, 2000; Ordóñez et al.
313 2006; Cantalamessa et al., 2007). The diagrams of relative age probability between actual and
314 40 Ma (Fig. 4) display, for most of the samples, a well defined young peak age corresponding
315 to the YDZ ages of the Angostura (for samples 13ECC12A, 12B, 07, 08, 34, and 16MCC06)
316 and Ónzole Formations (12ECC05, 07 and 18BCB02). For samples 13ECC04, 06, 11 and
317 16MCC03, we can note that the age distributions reveal a different pattern without a well-
318 defined young peak age and even a more smoothed distribution (especially for samples
319 13ECC04 and 06; Fig. 4). This feature could be related to the fact that all these sandstones
320 have been collected nearby faults (Jama, Tanigüe, Jipijapa/Cascol faults), which could locally
321 disturb the sediment supply and distribution. Indeed, it has been demonstrated that fault
322 activities can lead to the formation of structurally-controlled depocentres, a heterogeneous
323 pattern of accommodation space and sediment thickness (Brandes et al., 2007; Serck and
324 Braathen, 2018). Furthermore, synsedimentary faulting can as well disturb the sediment
325 gravity flow dynamics implying variation of the erosion behavior on short distances (less than
326 500 m; Pochat and Van Den Driessche, 2007). In the Coastal Cordillera of Ecuador, little is

327 known about the fault activity and motion range. Therefore, to define the real impact of these
328 faults on the sediment dynamics, a more detailed field study would be necessary.

329

330 **3.2.2 Apatite (U-Th-Sm)/He dating**

331 All samples display AHe ages ranging from 1.4 ± 0.1 to 53.9 ± 4.3 Ma, and most of
332 them are younger than the YDZ defined by U-Pb dating or even younger than the youngest
333 depositional ages defined by biostratigraphy (Table 2, 3 and Fig. 5) for the Angostura
334 Formation at 9.1 Ma by Cantalamessa et al. (2007). Our samples have been collected all along
335 the Coastal Cordillera, over a distance of 300 km. Each sample displays AHe ages younger
336 than the depositional age indicate that they have been at least partially reset. This general
337 pattern of partial reset over such a distance is reasonably explained by post-deposition burial,
338 reaching the partial retention zone (PRZ), which range from 40 to 120°C, depending on each
339 apatite diffusion coefficient and apatite crystal size (Shuster et al., 2006; Flowers et al., 2009;
340 Gautheron et al., 2009; Shuster & Farley, 2009; Brown et al., 2013; Ault et al., 2019). In
341 addition, some apatite crystals present higher AHe ages than the depositional age for low
342 effective Uranium content ($eU = U + 0.243Th + 0.0046Sm$) (Fig. 5). Those older AHe ages
343 with low eU content reflect the impact of alpha implantation by neighboring minerals
344 (Spiegel et al., 2009; Gautheron et al., 2012; Murray et al., 2014), especially when eU values
345 are below 20 ppm and ages over 10 Ma, following the exact pattern of the implantation model
346 prediction defined by Murray et al. (2014). In addition, the presence of defects or inclusions
347 (fluid or solid) (Recanati et al., 2017; Zeitler et al., 2017; McDannell et al., 2018) and the
348 chemical composition of apatite (Gautheron et al. 2013) could impact the AHe system. The
349 impact of radiation damage levels, approximated by the eU content of each dated grains
350 (Gautheron et al., 2009; Flowers et al., 2009), and the cumulative time span of the sample at a
351 very low temperature above the PRZ (see Ault et al., 2019 for a review) could play a

352 significant role if the sediments are not reset at enough temperature ($>80-100^{\circ}\text{C}$). However,
353 most of our data show only a slight apparent AHe age vs eU (or Th/U) correlation or AHe age
354 vs apatite size (Rs) and all the older AHe ages obtained seem to reflect alpha-implantation
355 impact (as identified in Fig. 5, A.2 and A.3).

356

357 **3.2.3 Modeling**

358 Obtained thermal histories and observed versus predicted AHe ages are reported in
359 Figure 6 and replaced along the topographic map of the Ecuadorian Coastal Cordillera.
360 Modeling used only AHe data that are not affected by alpha-implantation ($>10-12$ Ma).
361 Depositional constraints have been set up, taking into account our YDZ ages defined by U-Pb
362 dating. However, since the YDZ age could be older than the known stratigraphic position
363 (Copeland, 2020) we decided to use the youngest deposition age defined by biostratigraphy
364 (Benítez, 1995; Deniaud, 2000; Ordóñez et al. 2006; Cantalamessa et al., 2007).
365 Consequently, for samples 12ECC05, 12ECC07 and 18BCB02 the deposition period has been
366 estimated between 5-15 Ma, since the limit between the Angostura and Ónzole formations
367 remains unclear. For all the other samples, this constrain have been approximated at 9-15 Ma.

368 All the obtained thermal histories present consistent results, with predicted ages
369 (expected or maximum likelihood) in agreement with observed ages within error bars (Fig. 6).
370 The thermal histories of all samples record a post-depositional heating phase, before a final
371 cooling phase allowing the sample to crop out at the surface at the present time. Because all
372 the samples were reset or partially reset during this burial event, the pre-depositional histories
373 have been erased and thus the probability appears low and therefore, without real
374 signification. No specific spatial trends related to geographic positions of the samples (N-S or
375 E-W) is observed. The main differences between samples are the maximum heating
376 temperature that ranges from ~ 50 to $\sim 80^{\circ}\text{C}$ and the starting time for the last cooling phase.

377 Samples 12ECC05 and 12ECC07 display an exhumation path not very well constrained since
378 their depositional ages is close to the exhumation timing. Samples 13ECC07 and 16MCC06
379 show similar young exhumation histories at ~2 Ma for a max burial at ~50°C quite well
380 defined by a focused high relative probability of fit (red colored pixels in the model, Fig. 6).
381 Samples 18BCB02, 13ECC08, 13ECC12A+B and 16MCC03 recorded similar exhumation
382 timing around 5-6 Ma with burial reaching between ~60 and 80°C, relatively well
383 constrained. Samples 13ECC04, 13ECC06, 13ECC11 and 13ECC34 indicate an exhumation
384 at about 8-10 Ma with a burial around ~70-80 °C. The constraints on the model is acceptable
385 except for 13ECC04 where the dataset is almost impossible to converge toward a model
386 solution. The range of burial temperature obtained with the modeling is reasonable since the
387 depth of the Angostura formation can locally reach 2000 m (Fig. 3) and maybe even deeper in
388 the fault vicinities (Brandes et al., 2007; Serck and Braathen, 2018). Furthermore, the actual
389 geothermal gradient in Ecuador is estimated at >35 °C/km (Vieira and Hamza, 2019) and was
390 probably high as well during Neogene, implying a maximum burial of 2000-2500 m
391 according to our modeling results. The estimation of burial depths remains a rough
392 approximation because little is known about the fault magnitude of movement and
393 consequences on the sediment dynamics or the real geothermal gradient during Neogene.

394

395 **4. DISCUSSION**

396

397 **4.1. Stratigraphic age and provenance**

398 One of the keys of this study was to collect samples from the same stratigraphic level
399 to be able to compare the results from a geographic perspective and exhumation pattern, in the
400 aim to compare with the timing of the subduction of the Carnegie Ridge.

401 Zircon U-Pb dating has been carried out to confirm that samples were collected from
402 Angostura Formation. The YDZ ages show clearly that most of them are from this formation,
403 with ages ranging from 9.6 ± 0.2 Ma to 11.5 ± 0.6 Ma (Table 3), in agreement with previously
404 published biostratigraphic ages (Benítez, 1995; Deniaud, 2000; Ordóñez et al. 2006;
405 Cantalamessa et al., 2007). The variation observed in the age-distribution diagram probably
406 reflects the heterogeneities of the Angostura Formation in relation to structural discontinuities
407 related to fault systems present in the studied area. In particular, the Jama Fault may control
408 the spatial distribution of sediments (Reyes, 2013), which could explain the different age-
409 distribution patterns of samples 13ECC04 and 13ECC06. Similarly, for samples 13ECC07
410 and 16MCC03, the proximity of secondary faults (Fig. 2) could be responsible for their
411 slightly different age-distribution profiles.

412 Three samples (12ECC05, 12ECC07, 18BCB02) display younger ages and could be
413 attributed to the Ónzole Formation. However, the gradual transition between Angostura and
414 Ónzole formations (Deniaud, 2000; Reyes, 2013) does not permit to be certain that those
415 samples belong to one or the other formations. For this reason, the stratigraphic constraint
416 introduced into QTQt was set up at 5-15 Ma, for the three samples mentioned above and at 9-
417 10 Ma for all the other samples, to leave a maximum latitude to the software to reach a
418 solution (Fig. 6). In the case of sample 18BCB12, in order to make the data set converge to
419 find a solution, the modeling imposes a deposition age closer to ~ 10 Ma, whereas for
420 12ECC05 and 12ECC07 the deposition age would be closer to $\sim 5-6$ Ma (Fig. 6). Therefore,
421 sample 18BCB02 is probably from the Angostura Formation, near or in the transition to the
422 Ónzole Formation, while 12ECC05 and 12ECC07 are likely to belong to the Ónzole
423 Formation and have not been reset.

424

425 **4.2. Exhumation timing and implications**

426 The modeling results display three different timing of exhumation at ~2 Ma, ~5-6 Ma
427 and ~8-10 Ma for a burial which could reach a maximum temperature of ~80°C, without a
428 specific pattern related to the geographic position of the sample along the coast. The question
429 is how to interpret this result in the context of the Ecuadorian Coastal Cordillera.

430 The first stage of exhumation is recorded at ~8-10 Ma for three samples (13ECC06;
431 13ECC11, 13ECC34), all located close to fault systems (Fig. 2; Jama, Tanigüe and
432 Jipijapa/Cascol faults respectively). Most of the previous studies investigating rock
433 exhumation have been focused along the Andes (Witt et al., 2017, 2019), where widespread
434 cooling episodes has been reported for the last 25 Ma (Spikings and Crowhurst, 2004). One of
435 these events have been estimated between 15 and 9 Ma, using fission track analysis (Spikings
436 et al., 2001; Spikings and Crowhurst, 2004; Spikings et al., 2010; Spikings, and Simpson,
437 2014) and attributed to the collision of the Carnegie Ridge against the Ecuadorian margin
438 (Spikings et al., 2001; 2010). This could be an explanation, although all the samples
439 indicating an exhumation time at ~8-10 Ma are located in a fault vicinity while those
440 recording younger events are spread out all along the Coastal Cordillera. Therefore, this ~8-
441 10 Ma exhumation period could be the result of a tectonically controlled burial and
442 exhumation pattern locally enhanced by faults systems.

443 The second and third exhumation periods are defined at ~5-6 Ma and ~2 Ma,
444 respectively. Spikings and Crowhurst (2004) have identified, using apatite (U-Th-Sm)/He
445 thermal history models, similar cooling events at ~5.5-3.5 Ma and ~3.3-2.8 Ma in the
446 Cordillera Real of Ecuador (Fig. 1). Furthermore, an unconformity has been identified at
447 about ~5 Ma underlying the base of the Borbón Formation (Deniaud, 2000; Di Celma et al.,
448 2010) which has been considered as the Upper Ónzole Formation into the Borbón basin by
449 Reyes (2013). This represents a regional episode of hiatus or erosion in the Coastal Cordillera
450 (Deniaud, 2000). Low angular unconformities are described by Reyes (2013) in the Borbón

451 Formation and are interpreted as tectonic activity related to the Coastal Cordillera uplift.
452 Since that time, the paleo-bathymetry of the Borbón Formation has remained between
453 intertidal and neritic environments, revealing a shallowing of the seafloor, significant
454 sediment failure and mass-wasting, which occurred in response to the margin tilting (Di
455 Celma et al., 2010) and probably to the beginning of the Coastal Cordillera uplift.

456 The geodynamic environment of the Borbón Formation is consistent with the
457 exhumation timing revealed by our results, considering that this regional unconformity
458 described along the onshore forearc basins is also revealed along the offshore forearc domain
459 (Hernández et al., 2014; Hernández et al., 2020). Additionally, into the Esmeraldas submarine
460 canyon area (Fig. 1 and 2), Collot et al. (2019) evidences the development of the canyon by
461 several incision pulses, one of which is dated around ~5-6 Ma and correlated to an important
462 uplifting episode of at least 1 km, along the offshore forearc domain. Another is estimated to
463 take place during Pleistocene and is attributed to regional tectonic events.

464

465 **4.3. Geodynamic control of the Coastal Cordillera exhumation**

466 Convergence rate and obliquity of the Nazca plate motion relative to South America
467 plate during the last 25 Ma (Somoza and Ghidella, 2012) is characterized by ENE directed
468 convergence for a rate decreasing continuously from values at ~15 cm/yr during the Cenozoic
469 to present-day values around ~6-7 cm/yr. This sub-continuous decrease of the convergence
470 rates is not obviously correlated to discontinuous exhumation events inferring from our data
471 in the forearc domain. Cerpa and Arcay (2020) propose that, above a stagnating Nazca plate,
472 the slow-down of the absolute westward motion of the South-American continent in the last
473 25 Ma (Somoza and Ghidella, 2012) might contribute to the upward displacement of the
474 forearc area while the arc region subsides. This corresponds to the actual morphology of the
475 forearc and arc regions in Ecuador with the formation of the Coastal Cordillera while the arc

476 is located in the Interandine Depression. Therefore, it is possible to consider a global
477 kinematic cause for the forearc rise. It could be initiated ~25 Ma ago when the convergence
478 rate starts to decrease and recorded as an exhumation period at ~8-10 Ma in the forearc
479 region, since the time response to adjust kinematic changes of subduction could take between
480 10 to 35 Ma depending of the convergence rate variation (Cerpa et al., 2018). However, if a
481 global uplift of most of the coast along the South America margin is observed, the uplift rate
482 is enhanced where aseismic ridge is subducted (Martinod et al., 2016). In Ecuador, the
483 subduction of the Carnegie Ridge is then a possible booster for the upward displacement of
484 the forearc domain.

485 Debate persists regarding the geodynamic influence of subducting aseismic ridges on
486 the relief building along forearc domain. Henry et al. (2014), propose that the large-scale
487 geodynamic setting of subduction zones is of secondary importance to the uplift of the coastal
488 margin. Instead, the first order parameter is represented by the small-scale heterogeneities of
489 the subducting plate, as for instance, the subduction of aseismic ridges. Clift and Ruiz (2007)
490 suggest that temporary uplift due to arc-ridge collisions does not extend far landward from the
491 trench. In contrast, Espurt et al. (2007; 2010) and Gautheron et al. (2013b) illustrate its
492 influence until the Amazonian foreland basin. Morell (2016) shows the influence of the Cocos
493 ridge subduction (Costa Rica), from the trench inner wall to the volcanic arc.

494 In Ecuador, the subduction age for the Carnegie Ridge is controversial (Michaud et al., 2009)
495 and the morphology of the ridge subducted part is unknown and could have been much
496 different of what is currently observed. On the Nazca plate, the Carnegie Ridge exhibits in its
497 midst a topographic low (saddle) at 2400-m depth (Michaud et al., 2018), meanwhile the
498 segment which is close to the trench is at 700 m depth. Indeed, substantial along-strike relief
499 differences along the volcanic aseismic ridges are currently observed and when they enter into
500 subduction, they could produce different magnitudes of deformation in the forearc.

501 Consequently, we cannot rule out a scenario of an early arrival of the Carnegie Ridge, with a
502 smoother ancient ridge segment subducting at ~10-12 Ma, without causing dramatic
503 deformation in the forearc region, only activating some pre-existing structures (faults),
504 implying an exhumation at ~8-10 Ma. In this hypothesis, this segment, still buoyant enough,
505 would have influenced the slab dip angle as inferred from the arc eastward migration and
506 broadening at ~10-12 Ma (Schütte et al., 2010).

507 On the other hand, a reappraisal of Collot et al. (2009) model's about the initiation of
508 the Carnegie Ridge subduction using the plate convergence kinematic model of Nocquet et al.
509 (2014), suggests that the Carnegie Ridge entered in subduction ~5-6 Ma ago (Collot et al.,
510 2019). In this model, the northern flank of the Carnegie Ridge remains oblique in relation to
511 the trench direction. Assuming that the obliquity of the flank extends down to the slab, it
512 would imply that since ~5-6 Ma the Carnegie Ridge flank migrated southward along the
513 trench. The model of Collot et al. (2009) is compatible with both the location of the Carnegie
514 Ridge under the entire present-day Coastal Cordillera, and the exhumation timing obtained in
515 this work at ~5-6 Ma. After the initiation at ~5-6 Ma, subduction of sea-floor relief roughness
516 or thickened oceanic crust might have been responsible for heterogeneous uplift of the
517 Coastal Cordillera, as shown by our modeling with a Pleistocene exhumation event.

518 Consequently, the intermediate exhumation period, at ~5-6 Ma, could be related to the
519 Carnegie Ridge arrival into the trench or alternatively to the subduction of an along-strike
520 positive relief of the ridge. In the hypothesis of a ~5-6 Ma Carnegie Ridge arrival, subduction
521 erosion could explain the significant eastward migration of the volcanic arc region as
522 proposed by Schütte et al. (2010). Furthermore, kinematic changes could also support the
523 dynamics of the volcanics arc (Schütte et al., 2010).

524 Finally, the difficulty of identifying a geographic pattern for the different periods of
525 exhumation along the Coastal Cordillera is probably related to the fact that this area is

526 segmented by faults systems, deformed by folds, and still unstable. As a result, little is known
527 about the sediment thickness and its variations along the coast, or thermal status of the crust
528 during the Neogene, limiting the interpretation of our thermochronological data set.
529 Moreover, the unknown geometry of the subducted part of Carnegie Ridge as the
530 uncertainties about the age of the beginning of its subduction, are as many limitations to
531 studies reconstructing ridge-trench interactions by considering major deformation episodes in
532 the forearc domain.

533

534 5. CONCLUSIONS

535

536 New geochronology data (zircon U-Pb dating) allow us to define a range of maximum
537 deposition ages for the Angostura Formation from 9.6 ± 0.2 Ma to 11.5 ± 0.6 Ma and to
538 suggest that fault systems in the area may disturb the spatial distribution of sediments. The
539 QTQt modeling of our AHe dataset display three different timings of exhumation along the
540 Coastal Cordillera, independent of the sample geographic locations.

541 The oldest event, at $\sim 8-10$ Ma, evidenced locally along fault systems, can be
542 interpreted either in relation to regional overriding plate kinematic changes (slowdown of
543 absolute motion in the last ~ 25 Ma) or in response to smooth segment early arrival of the
544 Carnegie Ridge into the subduction.

545 An exhumation event at $\sim 5-6$ Ma has been identified and can be interpreted either as
546 the initiation timing of the Carnegie Ridge subduction or the subduction of an along-strike
547 positive relief of the ridge. Similarly, subduction of sea-floor relief roughness or thickened
548 oceanic crust could be responsible for heterogeneous uplift of the Coastal Cordillera during
549 the Pleistocene (~ 2 Ma) inducing exhumation as recognized in our modeling. The absence of
550 geographic pattern of exhumation along the studied area could be explained by variation of

551 sediment thickness and thermal status of the crust along the coast, especially since the area is
552 highly segmented by fault systems, deformed by folds and still highly unstable. However,
553 estimating the magnitude of the exhumation remains speculative since little is known about
554 the fault kinematics or the geothermal gradient during the Neogene.

555 Finally, our interpretations are corroborated by previous published studies and
556 demonstrate that the sensitivity of the apatite (U-Th-Sm)/He thermochronometer can provide
557 further constraints on the exhumation pattern in sedimentary domains.

560 This work was funded by the Institut de Recherche pour le Développement (IRD) and the
561 Institut National des Sciences de l'Univers (INSU; CNRS-INSU-SYSTER-2016). It was
562 carried out in the frame of the Proyecto Interno PII-DG-001-2015 (VIPSEPN) and Joint
563 French-Ecuador Laboratory “Earthquakes and Volcanoes in the Northern Andes”. We
564 acknowledge support from IRD/ANR MARACAS program (ANR-18-CE31-0022). We also
565 acknowledge support from IRD/ANR REMAKE program (ANR-15-CE04-0004) and
566 UCA/JEDI project (ANR-15-IDEX-01). M-J Hernández acknowledges support provided by
567 the Secretaría de Educación Superior, Ciencia, Tecnología e Innovación (SENESCYT), and
568 the Escuela Politécnica Nacional de Quito (EPN) through a PhD grant. We would like to
569 thank, for their technical support during sample preparations, Magali Bonnefoy and Mathieu
570 at Géosciences Azur and Sandrine Choy at Géosciences Environnement Toulouse, and during
571 the (U-Th-Sm)/He analysis, Rosella Pinna-Jamme at Geosciences Paris Saclay University.
572 Kerry Gallagher is thanked for the advices during QTQt modeling step. The editor Federico
573 Davila and the two reviewers Guido M. Gianni and Nick Perez are warmly thanked for their
574 constructive reviews.

575 **FIGURE CAPTIONS**

576

577 Figure 1: Elevation map of the Carnegie Ridge–Ecuador margin collision area (from Michaud
578 et al., 2006; size of the grid cell = 150 m). Offshore, the 2500 m isobath in black demarcates
579 the Carnegie Ridge. Inland, the isocontour in black demarcates the topography up to 200 m,
580 and the isocontour in red demarcates the topography up to 400 m. Stars are locations of great
581 subduction earthquake epicenters (from Nocquet et al., 2016).

582 In the left corner: Geodynamic framework where the Nazca plate motion related to South
583 American continent is from Trenkamp et al. (2002), the dotted black lines represent North
584 Andean Silver boundary, and the black rectangle indicates the studied area.

585

586 Figure 2: Simplified geologic map (location on Fig.1) from Reyes et Michaud (2012) of the
587 Ecuadorian Coastal Cordillera domain with location of the samples (back stars) dated in this
588 study.

589

590 Figure 3: Simplified litho-stratigraphic log of the Ecuadorian Coastal Cordillera (from Reyes,
591 2013)

592

593 Figure 4: Normalized U-Pb zircon age-distribution (relative age probability) diagram for the
594 entire dated sample between 0-40 Ma, ordered from north to south position. Diagram made
595 from routine available at www.geo.arizona.edu/alc and described in Gehrels, 2012.

596

597 Figure 5: A) Apatite He ages versus effective Uranium (eU) content diagram showing a
598 probable alpha implantation phenomenon for apatite crystals with young ages and low eU
599 content (coloured squares). B) Similar feature observed in an apatite He ages versus Th/U

600 ratio diagram. Each samples is identified by a different colour code. YDA stands for
601 Youngest Detrital Age for Angostura Formation (large dashed line) and Ónzole Formation
602 (narrow dashed line) estimated by biostratigraphy (Benítez, 1995; Deniaud, 2000; Ordóñez et
603 al. 2006; Cantalamessa et al., 2007).

604
605 Figure 6: QTQt thermal histories and observed vs predicted AHe ages, for each dated sample
606 replaced on the topographic map of the Coastal Cordillera of Ecuador (Faults and sample
607 locations are indicated, the red stars are for samples with depositional age between 9-15 Ma
608 while the orange stars are for deposition ages set up between 5-15 Ma). The expected model
609 (black line) represents the mean of each thermal histories that is used to calculate the
610 predicted age (black triangles). In addition, the colour scale presents the relative probability of
611 each thermal history, from deep blue (low probability) to red (high probability). The
612 maximum likelihood probability (orange line) of thermal history contains green to red colours
613 and the maximum likelihood predicted ages are also reported in the predicted-observed
614 inserted diagram (orange bars). For each model, the exhumation timing and the maximum
615 burial temperature are indicated under a similar colour code for each distinct period of
616 exhumation.

617

618 Table 1.: Sample information

619

620 Table 2.: Apatite (U-Th-Sm)/He data

621

622 Table 3.: Estimations of the youngest detrital zircon ages

623

624 **APPENDIX**

625 Figure A.1: U-Pb data in Wetherill Concordia diagrams with insert showing the youngest
626 zircon results.

627

628 Figure A.2: Apatite He ages versus effective Uranium (eU) content diagrams for every
629 individual sample showing a probable alpha implantation phenomenon for apatite crystals
630 with young ages and low eU content (coloured squares). YDA stands for Youngest Detrital
631 Age for Angostura Formation (large dashed line) and Ónzole Formation (narrow dashed line)
632 estimated by biostratigraphy (Benítez, 1995; Deniaud, 2000; Ordóñez et al. 2006;
633 Cantalamessa et al., 2007). Each samples is identified by a different colour code identical in
634 figures 5 and A.3.

635

636 Figure A.3: Apatite He ages versus Th/U ratio diagrams for every individual sample showing
637 a probable alpha implantation phenomenon for apatite crystals with young ages and low Th/U
638 ratio (coloured squares). YDA stands for Youngest Detrital Age for Angostura Formation
639 (large dashed line) and Ónzole Formation (narrow dashed line) estimated by biostratigraphy
640 (Benítez, 1995; Deniaud, 2000; Ordóñez et al. 2006; Cantalamessa et al., 2007). Each samples
641 is identified by a different colour code identical in figures 5 and A.2.

APPENDIX Table A.1. Zircon U-Pb dating operating conditions for LA-ICP-MS analyses

	ns-LA-HR-ICP-MS	fs-LA-HR-ICP-MS
Laboratory & Sample preparation		
Laboratory name	GeopSep Services	Géosciences Environnement Toulouse
Sample preparation	Polished mount	Polished mount
Sample type	Zircons	Zircons
Laser ablation system		
Make, Model & type	New Wave Neodymium: YAG 213	Laser nanosecond ESI NWR 213
Ablation cell	ESI NWR Single Volume	ESI NWR TwoVol2
Laserwavelength	193 nm	800 nm
Pulse width	< 5ns	< 5ns
Fluence	10 J/cm ²	4-4.6 J/cm ²
Repetition rate	5 Hz	10Hz
Spot size	20 µm (round spot)	30 µm (round spot)
Sampling mode / pattern	Single spot	Single spot
Carrier gas	100% He and Ar make-up gas	100% He and Ar make-up gas
Background collection	6 seconds	15 seconds
Ablation duration	24 seconds	30 seconds
Wash-out delay	20 seconds	20 seconds
Cell carrier gas flow (He)	0.8 l/min	0.8 l/min
ICP-MS Instrument		
Make, Model & type	Finnigan Element II Magnetic Sector	Thermo-Fisher Element-XR, HR-ICP-MS
Sample introduction	Via conventional tubing	Via conventional tubing
RF power	1250 W	1280 W
Sampler, skimmer cones	Ni	Ni
Extraction lenses	X type	X type
Make-up gas flow (Ar)	1 l/min	1 l/min
Detection system	Single collector secondary electron multiplier	Single collector secondary electron multiplier
Data acquisition protocol	Time-resolved analysis	Time-resolved analysis
Scanning mode	Peak hopping, one point per peak	Peak hopping, one point per peak
Detector mode	Pulse counting, dead time correction applied, and analog mode when signal intensity > ~ 10 ⁶ cps	Pulse counting, dead time correction applied, and analog mode when signal intensity > ~ 10 ⁶ cps
Masses measured	²⁰² Hg, ²⁰⁴ Pb, ²⁰⁶ Pb, ²⁰⁷ Pb, ²⁰⁸ Pb, ²³⁸ U, ²³⁵ U, ²³² Th	²⁰⁸ Pb, ²³⁸ U, ²³⁵ U, ²³² Th
Sensitivity / Efficiency	3 10 ⁷ cps/ppm ²³⁸ U (20µm, 5 Hz)	3 10 ⁷ cps/ppm ²³⁸ U (20µm, 10 Hz)
Dwell time per isotope	24 ms	40 ms
Data Processing		
Gas blank	20 seconds on peak	15 seconds on peak
Calibration strategy	Duluth complex (FC1) / Fish Canyon Tuff / Tardree Rhyolite / Mt. Dromedary	91500 zircon / Fish Canyon zircon / Nist 610 SRM 610 ref. glass
Reference Material info	FC (Paces and Miller, 1993) / Fish Canyon (Kuiper et al., 2008) / Tardree (Ganerød et al., 2011) / Mt. Dromedary (Renne et al., 1998)	91500 (Wiedenbeck et al. 1995) / Fish Canyon Tuff (Kuiper et al., 2008) / Plesovice (Sláma et al., 2008)
Data Processing package	-	lolite (Paton et al., 2010)
Quality control / Validation (Ages = 206Pb/238U weighted average)	FC1 = 1097.8 ± 9.5 Ma / Tardree = 60.2 ± 0.9 Ma / Fish Canyon = 29.8 ± 0.4 Ma / Mt. Dromedary = 100.1 ± 1.5 Ma	Fish Canyon = 28.8 ± 0.2 (MSWD = 1.3) / Plešovice zircon = 338,7 ± 1.1 Ma (MSWD = 0.9)

Ganerød, M., Chew, D. M., Smethurst, M. A., Troll, V. R., Corfu, F., Meade, F., Prestvik, T., 2011. Geochronology of the Tardree Rhyolite Complex, Northern Ireland: Implications for zircon fission track studies, the North Atlantic Igneous Province and the age of the Fish Canyon sanidine standard. (U-Th)/He ages were performed by laser heating for He extraction and ICP-MS for U-Th determinations at GEOPS Université Paris Sud, France. The estimated analytical uncertainty for He ages is about 8% (2σ). eU is the effective uranium = $U + 0.243Th + 0.0046Sm$.

Table 3. Estimations of the youngest detrital zircon ages.

Sample Name	Number of grain in cluster	Age (Ma)	$\pm 2\sigma$ (Ma)	MSWD	Youngest concordant single age*
12ECC05	17	7.0	0.3	1.2	7.6 \pm 1.1 Ma
12ECC07	20	7.1	0.2	1.9	6.7 \pm 0.3 Ma
13ECC04	2	10.3	0.4	0.0	10.1 \pm 0.5 Ma
13ECC06	13	11.5	0.6	1.4	10.8 \pm 0.8 Ma
13ECC07	22	10.7	0.2	1.1	10.3 \pm 0.6 Ma
13ECC08	48	9.8	0.3	2.0	9.5 \pm 1.1 Ma
13ECC11	22	9.9	0.4	1.3	9.4 \pm 0.9 Ma
13ECC12A	23	9.6	0.3	1.4	8.6 \pm 0.8 Ma
13ECC12B	38	9.6	0.2	1.2	9.5 \pm 1.0 Ma
13ECC34	23	9.6	0.3	1.5	8.6 \pm 0.7 Ma
16MCC03	22	10.0	0.4	1.8	9.4 \pm 0.8 Ma
16MCC06	35	10.7	0.2	1.0	10.3 \pm 0.6 Ma
18BCB02	11	7.7	0.3	4.5	21.0 \pm 0.8 Ma

Systematic error estimated at 2.5%

*at <15% maximum of discordancy

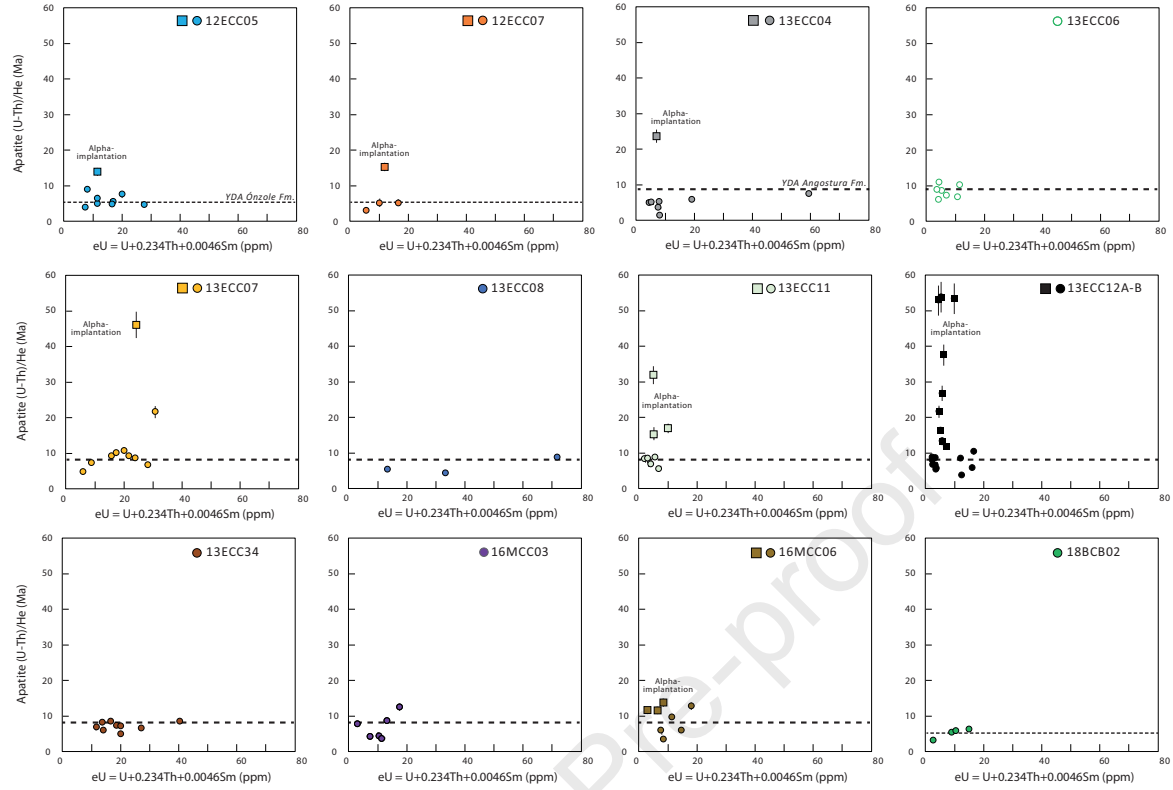

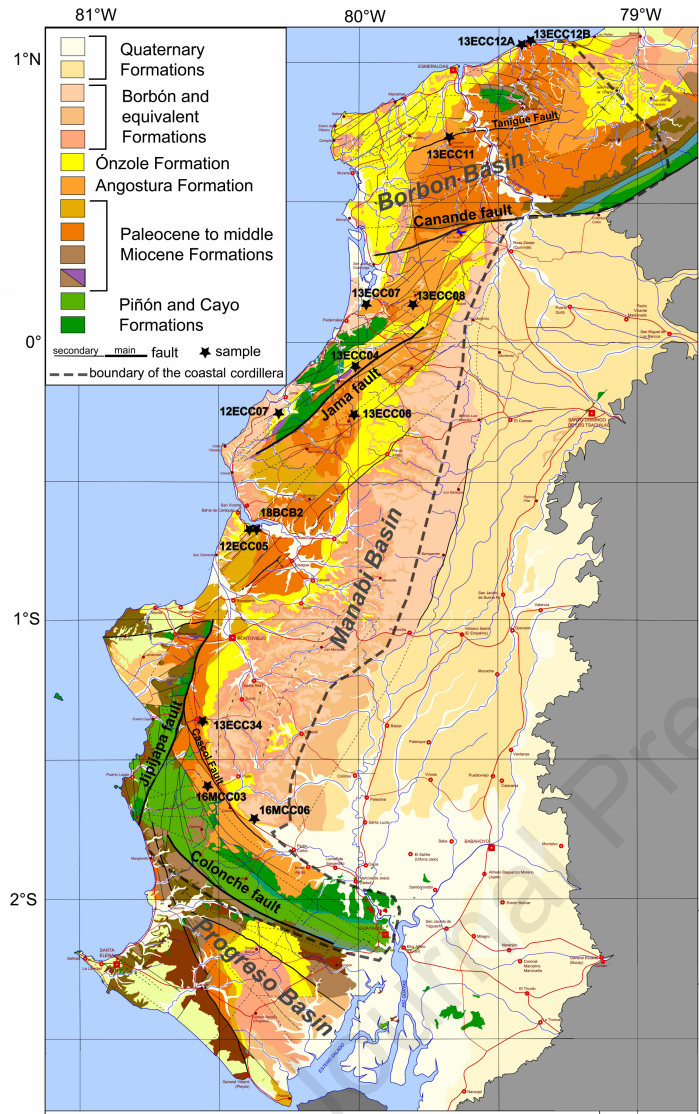

Figure A.1: Concordia plot of all the samples analyzed (see the Table A.1 for the data). In some concordia plot, a focus on the younger zircons (< 200 Ma) has been carried out. Error ellipses are at 2σ .

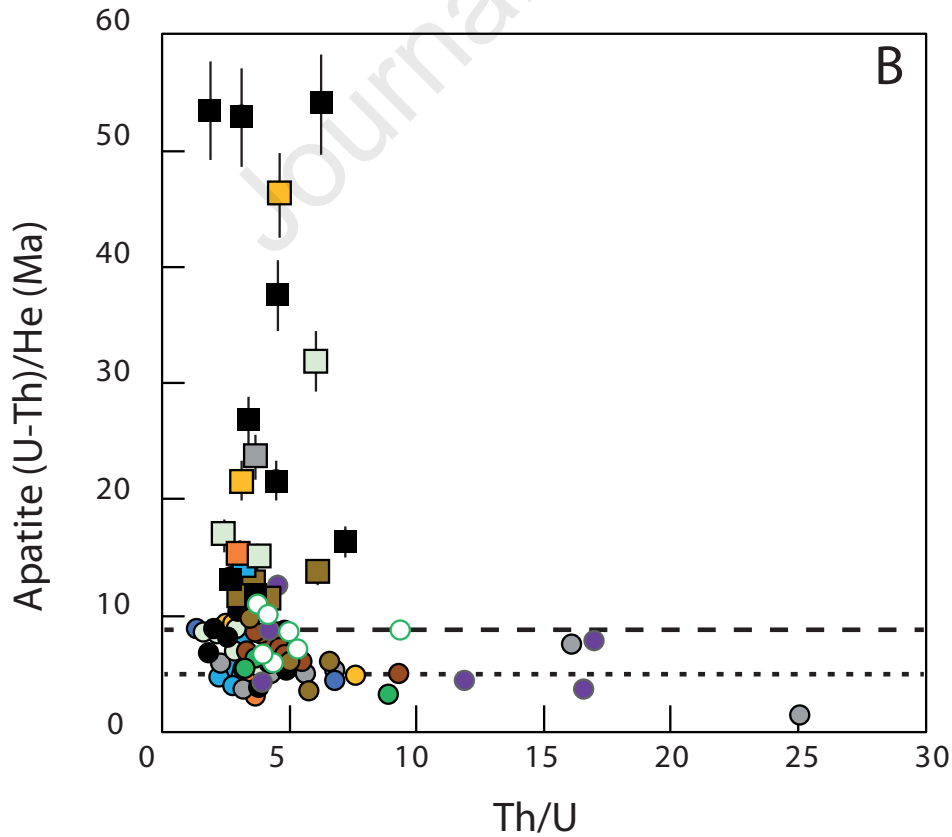

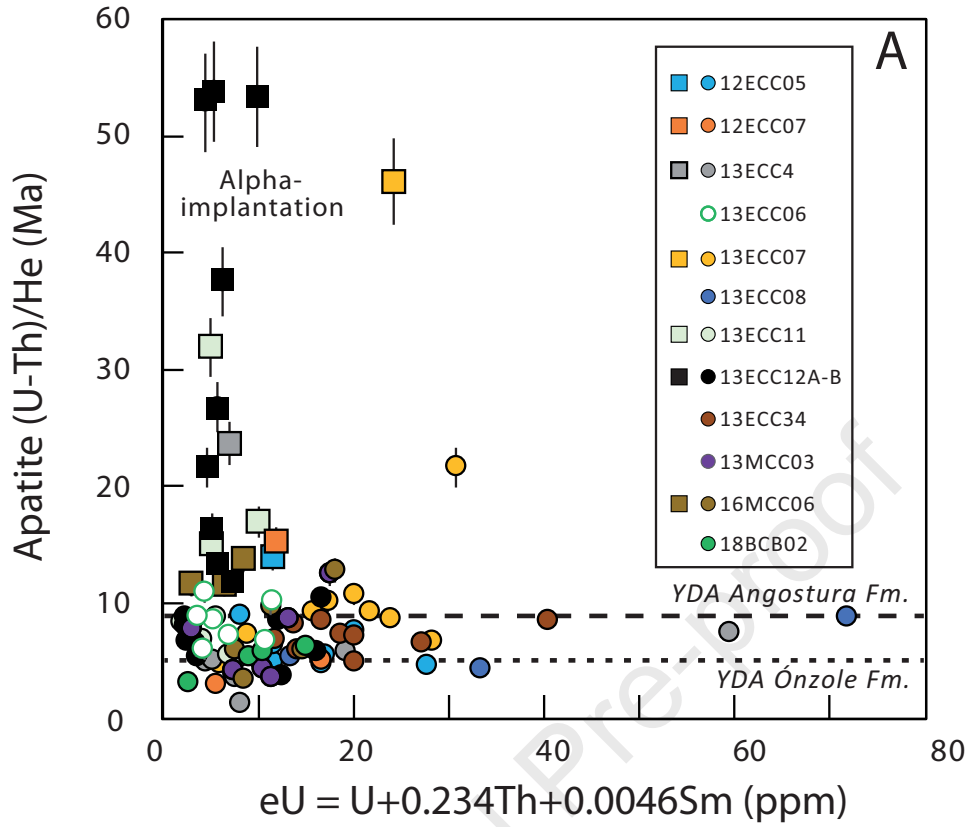

- Three main periods of exhumation have been recognized in the Coastal Cordillera of Ecuador
- Overriding plate kinematic changes can play a significant role in exhumation processes
- The Apatite (U-Th-Sm)/He thermochronometer is sensitive enough to provide reliable constraints in sedimentary domains

Journal Pre-proof

AUTHORS STATEMENT FOR PUBLICATION

Manuscript title: **First timing constraints on the Ecuadorian Coastal Cordillera exhumation: geodynamic implications**

Corresponding author's full name: **Stephanie Brichau**

Please note that all contributing authors are obligated to sign *Authors statement for publication* form otherwise the manuscript will not be published.

Please fill in the table below according to following:

- *list the authors in order in which they are stated in manuscript. This way each author is assigned with number for further identification.*
- *each author should sign this document (on designated place in the table). By signing this form authors take full responsibility for all statements it contains.*

No.	Author's full name (in capital letters)	Author's signature
1.	Stephanie Brichau	
2.	Pedro Reyes	
3.	Cecile Gautheron	
4.	Maria José Hernandez	
5.	François Michaud	
6.	Mathieu Leisen	
7.	Arnaud Vacherat	
8.	Marianne Saillard	
9.	Jean-Noel Proust	
10.	Paul O'Sullivan	

AUTHORSHIP STATEMENT:

According to International Committee of Medical Journal Editors (ICMJE): "An author is considered to be someone who has made substantive intellectual contributions to a published study. An author must take responsibility for at least one component of the work, should be able to identify who is responsible for each other component, and should ideally be confident in their co-authors' ability and integrity. " (available at: http://www.icmje.org/ethical_1author.html)

Please fill the table with numerical code of each author (from the before signed table) regarding authors contribution to specific component of research.

Component of the research	Author's number
substantial contribution to conception and design	1, 2, 4, 5, 8, 9
substantial contribution to acquisition of data	1, 3, 6, 7, 10
substantial contribution to analysis and interpretation of data	1, 2, 3, 4, 5, 6, 7
drafting the article	1, 2, 3, 5, 7
critically revising the article for important intellectual content	1, 2, 3, 4, 5, 6, 7, 8, 9
final approval of the version to be published	1, 2, 3, 4, 5, 6, 7, 8, 9, 10

Please tick the box if the statement applies:

- to the best of your knowledge everybody who participated substantially in the study is not omitted from the article
- to the best of your knowledge, all persons listed as authors qualify for authorship

All persons who have made substantial contributions to the work but do not meet the criteria for authorship are listed in Acknowledgments section (technical help, writing assistance, general support, financial and material support)

Yes No

All persons named in the Acknowledgment section of the manuscript have given their permission to be named

Yes No

ORIGINALITY OF THE WORK STATEMENT:

Editorial board of the journal: Medical Archives; Materia Socio-medica or Acta Informatica Medica strongly promotes research integrity and aims to prevent any type of scientific misconduct according to Committee on Publication Ethics (COPE) flowcharts. (available at: <http://publicationethics.org/resources/flowcharts>)

Please tick the box if the following statements are correct to the best of your knowledge:

- the manuscript is not previously published in the same or very similar form in other journal (previous publishing does not apply to abstract or poster presentations at a professional meeting)
- the manuscript is not currently under consideration in other journals (that does not apply for manuscripts that have been rejected by other journals)

Date (dd/mm/yyyy)

Corresponding author's signature
